# GENERALIZED BASES FOR THE REAL NUMBERS 

J. A. Fridy, Rutgers - The State University, New Brunswick, New Jersey

Throughout this paper $\left\{r_{i}\right\}_{1}^{\infty}$ will denote a non-increasing real number sequence with limit zero; each of $\left\{\mathrm{k}_{\mathrm{i}}\right\}_{1}^{\infty}$ and $\left\{\mathrm{m}_{\mathrm{i}}\right\}_{1}^{\infty}$ denotes a non-negative integer sequence

$$
S=\sum_{1}^{\infty} k_{i} r_{i} \quad \text { and } \quad S^{*}=\sum_{1}^{\infty} m_{i} r_{i}
$$

(finite or infinite). We shall consider the possibility of expressing each number x in the interval $\left(-\mathrm{S}^{*}, \mathrm{~S}\right)$ in the form

$$
x=\sum_{i}^{\infty} a_{i} r_{i}
$$

where each $a_{i}$ is an integer satisfying $-m_{i} \leq a_{i} \leq k_{i}$.
In the classical $n$-scale number representation, each x in $[0,1]$ can be expressed in the above form, where $n>1$, and $r_{i}=n^{-i}, k_{i}=n-1$,
 sidered only the expansion of positive numbers with certain restrictions on the coefficient bounds $\left\{\mathrm{k}_{\mathrm{i}}\right\}_{1}^{\infty}$.

In this note we shall extend the previous work to include negative number representations as well as relaxing the restrictions on the coefficients $\left\{\mathrm{a}_{\mathrm{i}}\right\}_{1}^{\infty}$. We shall also consider the question of uniqueness of such representations and the expansion of real numbers using a base sequence $\left\{ \pm r_{i}\right\}_{1}^{\infty}$ of both positive and negative terms.

DEFINITION. The sequence $\left\{r_{i}\right\}_{1}^{\infty}$ is a $\{k, m\}$-base for the interval $\left(-S^{*}, S\right)$ if for each $x$ in $\left(-S^{*}, S\right)$ there is an integer sequence $\left\{a_{i}\right\}_{1}^{\infty}$ such that

$$
\begin{equation*}
x=\sum_{i}^{\infty} a_{i} r_{i}, \quad \text { and } \quad-m_{i} \leq a_{i} \leq k_{i} \quad \text { for each } i_{0} \tag{1}
\end{equation*}
$$

Our main purpose is to develop an explicit characterization of a $\{k, m\}-$ base; to this end we first consider the case where $m_{i}=0$ for each $i$; i. e., a $\{\mathrm{k}, 0\}$-base.

LEMMA. The sequence $\left\{\mathrm{r}_{\mathrm{i}}\right\}_{1}^{\infty}$ is a $\{\mathrm{k}, 0\}$-base for the interval $(0, \mathrm{~S})$ if and only if

$$
\begin{equation*}
r_{n} \leq \sum_{n+1}^{\infty} k_{i} r_{i} \quad \text { for each } n \tag{2}
\end{equation*}
$$

Proof. If (2) does not hold and

$$
r_{n}>x>\sum_{n+1}^{\infty} k_{i} r_{i}
$$

for some $n$, it is easily seen that $x$ cannot be expressed in the form (1).
Assume that (2) holds and let $x$ be in ( $0, S$ ), the conclusion being trivial for $x=0$. Let $i(1)$ be the least positive integer such that $r_{i(1)} \leq x$, and choose $a_{i(1)}$ to be the greatest integer such that $a_{i(1)} \leq k_{i(1)}$ and $a_{i(1)}{ }^{r}{ }_{i(1)}$ $\leq \mathrm{x}$ 。

If $a_{i(1)} r_{i(1)}<x$, we continue inductively:
Let $i(n)$ be the least positive integer such that

$$
\begin{equation*}
r_{i(n)} \leq x-\sum_{p=1}^{n-1} a_{i(p)} r_{i(p)} \quad \text { and } \quad i(n)>i(n-1) ; \tag{3}
\end{equation*}
$$

Choose $a_{i(n)}$ to be the greatest integer such that $a_{i(n)} \leq k_{i(n)}$ and

$$
\begin{equation*}
a_{i(n)^{r}}{ }_{i(n)} \leq x-\sum_{p=1}^{n-1} a_{i(p)} r_{i(p)} \tag{4}
\end{equation*}
$$

In case equality does not hold in (4) for any $n$, we assert that
(5)

$$
\sum_{p=1}^{\infty} a_{i(p)^{r}}{ }_{i(p)}=x
$$

Suppose, to the contrary, that for some positive $\epsilon$

$$
\sum_{p=1}^{n} a_{i(p)} r_{i(p)} \leq x-\epsilon, \text { for each } n
$$

If $r_{i(n)}<\epsilon$ it follows that

$$
\begin{equation*}
\left(a_{i(n)}+1\right) r_{i(n)} \leq x-\sum_{p=1}^{n-1} a_{i(p)} r_{i(p)} \tag{6}
\end{equation*}
$$

By the choice of $a_{i(n)}$ this implies that $a_{i(n)}=k_{i(n)}$; furthermore, (6) also yields

$$
r_{i(n)+1} \leq r_{i(n)} \leq x-\sum_{p=1}^{n} a_{i(p)} r_{i(p)}
$$

so that $i(n+1)=i(n)+1$ 。 Hence,
(7) $\sum_{p=1}^{\infty} a_{i(p)} r_{i(p)}=\sum_{p=1}^{n-1} a_{i(p)} r_{i(p)}+\sum_{p=i(n)}^{\infty} k_{p} r_{p} \leq x$.

Applying (2) to (7) we see that

$$
\begin{equation*}
r_{i(n)-1} \leq x-\sum_{p=1}^{n-1} a_{i(p)} r_{i(p)} \tag{8}
\end{equation*}
$$

By the choice of $i(n)$, (8) implies that $i(n)-1=i(n-1)$, so that (8) can be written as

$$
\left(a_{i(n-1)}+1\right) r_{i(n-1)} \leq x-\sum_{p=1}^{n-2} a_{i(p)} r_{i(p)}
$$

whence $a_{i(n-1)}=k_{i(n-1)^{\circ}}$. Thus it is readily seen that for every $n, i(n)=n$ and $\mathrm{a}_{\mathrm{i}(\mathrm{n})}=\mathrm{k}_{\mathrm{n}}$, which contradicts $\mathrm{x}<\mathrm{S}$; this establishes (5) and completes the proof.

REMARK. From this Lemma the following is clear:
If $\left\{r_{i}\right\}_{1}^{\infty}$ is a $\{k, 0\}$-base for $[0, S)$ and $N$ is a positive integer, then $\left\{r_{i}\right\}^{\infty}{ }_{N}$ is a $\{\mathrm{k}, 0\}_{\mathrm{N}}^{\infty}$-base for the interval

$$
\left[0, \sum_{\mathrm{N}}^{\infty} \mathrm{k}_{\mathrm{i}} \mathrm{r}_{\mathrm{i}}\right)
$$

Theorem 1. The sequence $\left\{\mathrm{r}_{\mathrm{i}}\right\}_{1}^{\infty}$ is a $\{\mathrm{k}, \mathrm{m}\}$-base for $\left(-\mathrm{S}^{*}, \mathrm{~S}\right)$ if and only if

$$
\begin{equation*}
r_{n} \leq \sum_{i=n+1}^{\infty}\left(k_{i}+m_{i}\right) r_{i} \quad \text { for each } n \tag{9}
\end{equation*}
$$

Proof. If (9) does not hold and

$$
r_{n}>x>\sum_{n+1}^{\infty}\left(k_{i}+m_{i}\right) r_{i}
$$

it follows easily from the Lemma that $x-S^{*}$ is in $\left(-S^{*}, S\right)$ but $x-S^{*}$ cannot be expressed as in (1).

To show the sufficiency of (9) we first consider the case where $S^{*}$ is finite. Let $x$ be in $\left(-S^{*}, S\right)$. By the Lemma, (9) guarantees a sequence $\left\{a_{i}\right\}_{1}^{\infty}$
such that

$$
x+S^{*}=\sum_{1}^{\infty} a_{i} r_{i}, \quad \text { and } \quad 0 \leq a_{i} \leq k_{i}+m_{i} \quad \text { for each } i
$$

Letting $b_{i}=a_{i}-m_{i}$ ，we have

$$
x=\sum_{1}^{\infty} b_{i} r_{i}, \quad \text { and } \quad-m_{i} \leq b_{i} \leq k_{i} \quad \text { for each } i
$$

The case in which $S$ is finite is proved similarly．If both $S^{*}$ and $S$ are infinite it follows immediately from the Lemma that every non－negative x can be expressed as

$$
\sum_{i}^{\infty} a_{i} r_{i}
$$

where $0 \leq \mathrm{a}_{\mathbf{i}} \leq \mathrm{k}_{\mathrm{i}}$ ，and every negative x can be so expressed with $-\mathrm{m}_{\mathrm{i}} \leq \mathrm{a}_{\mathrm{i}}$ $\leq 0$ 。

We now wish to establish conditions under which the representations in the form（1）are unique．Since the common decimal expansion is not unique，and this is the special case where $r_{i}=10^{-i}, m_{i}=0$ ，and $k_{i}=9$ ，we cannot hope for total uniqueness in any non－trivial case．Therefore we adopt a con－ vention similar to that used in identifying the decimal 。0999。o with $.1000 \ldots$ ， viz．，we disallow a representation in which $a_{i}=k_{i}$ for every $i$ greater than some $n_{0}$ ．Note that in the proof of the Lemma such representations were not necessary．（This is also the reason that we did not consider the closed inter－ val［ $0, S$ ］even when $S$ was finite．

Theorem 2．The sequence $\left\{x_{i}\right\}_{1}^{\infty}$ yields exactly one $\{k, m\}$－base repre－ sentation of each $x$ in（ $-S^{*}, S$ ）if and only if

$$
\begin{equation*}
r_{n}=\sum_{i=n+1}^{\infty}\left(k_{i}+m_{i}\right) r_{i} \quad \text { for each } n \tag{10}
\end{equation*}
$$

Proof. The sufficiency of (10) is fairly straightforward. Conversely, it is easily seen that for unique representation it is necessary that $S^{*}$ (and $S$ ) be finite。Suppose that $S^{*}$ is finite and $\left\{r_{i}\right\}_{1}^{\infty}$ satisfies (9) but not (10). Then there exists an integer $n$ and a number $x$ such that

$$
r_{n}<x<\sum_{n+1}^{\infty}\left(k_{i}+m_{i}\right) r_{i}
$$

Using the construction in the proof of the Lemma, we get a sequence $\left\{\mathrm{a}_{\mathrm{i}}\right\}_{1}^{\infty}$ satisfying

$$
x=\sum_{1}^{\infty} a_{i} r_{i}
$$

and $0 \leq a_{i} \leq k_{i}+m_{i}$; moreover, since $r_{n}<x$, at least one of $a_{1}, \cdots, a_{n}$ is non-zero. Taking $b_{i}=a_{i}-m_{i}$, we have

$$
\begin{equation*}
x-s^{*}=\sum_{1}^{\infty} b_{i} r_{i}, \quad \text { where }-m_{i} \leq b_{i} \leq k_{i} \tag{11}
\end{equation*}
$$

and for some $i \leq n, \quad b_{i} \neq-m_{i}$.
On the other hand $\left\{r_{i}\right\}_{n+1}^{\infty}$ is a $\{k+m, 0\}_{n+1}^{\infty}$-base for the interval

$$
\left[0, \sum_{n+1}^{\infty}\left(k_{i}+m_{i}\right) r_{i}\right)
$$

by the Remark following the Lemma. This yields a second $\{k, m\}$-base representation: $x-s=\sum_{1} d_{i} r_{i}$, where $d_{i}=-m_{i}$ for all $i \leq n_{\text {. }}$

COROLLARY. The sequence $\left\{r_{i}\right\}_{1}^{\infty}$ yields a unique $\{\mathrm{k}, \mathrm{m}\}$-base representation of each $x$ in $\left(-S^{*}, S\right)$ if and only if

$$
r_{n}=\left(S+S^{*}\right) / \Pi_{i=1}^{n}\left(1+k_{i}+m_{i}\right) \quad \text { for each } n
$$

Proof. This is straightforward induction using Theorem 2.
The foregoing theory can be used to consider representations of real numbers in which the base sequence $\left\{r_{i}\right\}_{1}^{\infty}$ takes on both positive and negative values. Let $A$ and $B$ be disjoint sets whose union is the set of positive integers, and let $C_{A}$ and $C_{B}$ denote their respective characteristic functions. We shall use

$$
\left\{(-i){ }^{C_{B}^{(i)}}{ }^{r_{i}}\right\}_{i}^{\infty}
$$

as the base sequence。
Theorem 3. If $\left\{q_{i}\right\}_{1}^{\infty}$ is a positive integer sequence, then

$$
\left\{(-1){ }^{C_{B}^{(i)}}{ }_{r i}\right\}_{1}^{\infty}
$$

is a $\{q, 0\}$-base for the interval

$$
\left(-\sum_{i \in B} q_{i} r_{i}, \quad \sum_{i \in A} q_{i} r_{i}\right)
$$

if and only if

$$
\begin{equation*}
r_{n} \leq \sum_{n+1}^{\infty} q_{i} r_{i} \quad \text { for each } n \tag{12}
\end{equation*}
$$

Proof. Let $k_{i}=C_{A}(i) q_{i}$ and $m_{i}=C_{B}{ }^{(i) q_{i}}$, so that $k_{i}+m_{i}=q_{i}$, $\Sigma_{i \in A} q_{i} r_{i}=S$, and $\Sigma_{i \in B} q_{i} r_{i}=S_{0}^{*}$ Thus by Theorem 1, (12) is equivalent to $\left\{r_{i}\right\}_{1}^{\infty}$ being a $\{k, m\}-$ base for $\left(-S^{*}, S\right)$. If (12) holds and $x$ is in $\left(-S^{*}, S\right)$, then

$$
x=\sum_{1}^{\infty} b_{i} r_{i} \text {, where }-C_{B}(i) q_{i} \leq b_{i} \leq C_{A}(i) q_{i}
$$

Taking $a_{i}=(-1){ }^{C_{B}(i)} b_{i}$ ，we have

$$
\begin{equation*}
\sum_{1}^{\infty} a_{i}\left[{ }_{(-1)}{ }^{C_{B}^{(i)}} r_{i}\right] \quad \text { and } \quad 0 \leq a_{i} \leq q_{i} \tag{13}
\end{equation*}
$$

The converse is proved similarly。
REMARK．It is clear that the representations in（13）are unique if and only if equality holds in（12）for each $\mathrm{n}_{\text {。 }}$

A related problem is that of expressing a given number x in the form

$$
\begin{equation*}
\mathrm{x}=\sum_{1}^{\infty} \epsilon_{\mathrm{i}} \mathrm{r}_{\mathrm{i}}, \quad \text { where } \quad \epsilon_{\mathrm{i}}=1 \text { or }-1 \tag{14}
\end{equation*}
$$

The following solution is proved using Theorem 1.
PROPOSITION。 If

$$
r_{n} \leq \sum_{n+1}^{\infty} r_{i} \quad \text { for each } n, \text { and }|x| \leq \sum_{1}^{\infty} r_{i}
$$

1
then $x$ can be expressed in the form（14）．
The special case of Theorem 1 in which $k_{i}=1$ and $\dot{m}_{i}=0$ ，for all $i$ ， is apparently an old result first proved by Kakeya［7］（cf．［2］）．Generalizations of the $n$－scale（radix $n$ ）representation of positive integers which are anal－ ogous to the theory presented here have been developed by Alder［1］and Brown ［3－5］．

## A.NNOUNCEMENT

The Journal of Combinatorial Theory will be devoted to the publication of original mathematical articles dealing with theoretical and physical aspects of the study of finite and discrete structures in all branches of science. It will fully explore the long-neglected field of combinatorial analysis - a field which has only now begun to realize its potential. The Journal will include the efforts of scientists, working in many independent disciplines, who have discovered a common link through combinatorics. Mathematicians, biologists, physicists, and engineers will find this Journal a central reference for the combinatorial methods which are increasingly important to many of their main problems. # ON A PARTIAL DIFFERENCE EQUATION OF L. CARLITZ 

W. Jentsch, University of Halle /S., Germany

Translated by: P.F. Byrd and Monika Aumann, San Jose State College, San Jose, Calif.

## SUMMARY

Eine von L. CARLITZ behandelte partielle Differenzengleichung zweiter Ordnung, die mit den FIBONACCI-Zahlen in Beziehung steht, wird mit Hilfe einer algebraisch begründeten, zweidimensionalen Operatorenrechnung gelöst. Die sich hierbei ergebende Lösung ist allgemeiner als diejenige von L. CARLITZ.

In an article [1] by L. Carlitz, a solution of the equation

$$
\begin{align*}
u_{m n}-u_{m-1, n}-u_{m, n-1}-u_{m-2, n}+3 u_{m-1, n-1}-u_{m, n-2} & =0  \tag{1}\\
(m, n & \geq 2, \text { integral })
\end{align*}
$$

was given with the aid of a power series expansion related to the Fibonacci numbers. Although the solution contains only three arbitrary constants (viz. , $u_{00}, u_{01}$, and $u_{10}$ ), it is called a "general solution" - a terminology which appears justified only if, besides equation (1), the following secondary conditions, not mentioned in [1], are also imposed:

$$
\begin{align*}
& u_{11}-u_{01}-u_{10}+3 u_{00}=0,  \tag{2}\\
& u_{0 n}-u_{0, n-1}-u_{0, n-2}=0 \text { for } n \geq 2,  \tag{3}\\
& u_{m 0}-u_{m-1,0}-u_{m-2,0}=0 \text { for } m \geq 2,  \tag{4}\\
& u_{1 n}-u_{0 n}-u_{1, n-1}+3 u_{0, n-1}-u_{1, n-2}=0 \text { for } n \geq 2,  \tag{5}\\
& u_{m 1}-u_{m-1,1}-u_{m 0}-u_{m-2,1}+3 u_{m-1,0}=0 \text { for } m \geq 2 . \tag{6}
\end{align*}
$$

The conclusion (1.4) from [1] is valid only under the assumptions (2) to (6). From (2), $u_{11}$ is fixed, and from (3) to (6) the initial values $u_{0 n}, u_{1 n}$ and $u_{m 0}, u_{m 1}$ are uniquely determined for $n, m \geq 2$. The general solution of (3), for instance, is

$$
\begin{equation*}
u_{0 \mathrm{n}}=\mathrm{u}_{01} \mathrm{~F}_{\mathrm{n}}+\mathrm{u}_{00} \mathrm{~F}_{\mathrm{n}-1} \quad \text { for } \mathrm{n} \geq 0 \tag{7}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{F}_{\mathrm{n}}=\frac{\alpha^{\mathrm{n}}-\beta^{\mathrm{n}}}{\alpha-\beta} \quad \text { with } \quad \alpha=\frac{1}{2}(1+\sqrt{5}), \quad \beta=\frac{1}{2}(1-\sqrt{5}) \quad \text { (n integral). } \tag{8}
\end{equation*}
$$

One can easily verify that the solution (5.4) given by L. Carlitz in [1] reduces to equation (7) for $m=0$.

The general solution of (1) without secondary conditions thus contains two pairs of arbitrary functions of only one of the two integral variables $m$ and $n$. We now wish to determine this solution with the aid of the "two-dimensional, discrete operational calculus" developed in [2].

According to the fundamental idea of J. Mikusinski (see perhaps [3]), the usual addition and the two dimensional Cauchy product
(9) $\quad \mathrm{a}_{\mathrm{mn}} \cdot \mathrm{b}_{\mathrm{mn}}=\sum_{\mu, v=0}^{\mathrm{m}, \mathrm{n}} \mathrm{a}_{\mu \nu} \mathrm{b}_{\mathrm{m}-\mu, \mathrm{n}-v} \quad$ as multiplication
are introduced in the set of complex-valued functions of two nonnegative integral variables, and the quotient field $Q_{2}$ belonging to the integral domain $D_{2}$ arising from this means is considered. In order to conform with the relations in [2], we make an index shift in (1) and write
(1') $D\left(u_{m n}\right)=u_{m+2, n+2}-u_{m+1, n+2}-u_{m+2, n+1}-u_{m, n+2}+3 u_{m+1, n+1}$

$$
-u_{m+2, n}=0 \quad(m, n \geq 0)
$$

After application of the difference theorem from [2],

$$
\begin{aligned}
& u_{m+k, n+\ell}=p^{k} q^{l} u_{m n}-q^{l} \sum_{\kappa=0}^{k-1} p^{k-\kappa} u_{\kappa n}-p^{k} \sum_{\lambda=0}^{\ell-1} q^{l-\lambda} u_{m \lambda}+ \\
& \sum_{\sum_{k=0}^{k-1} \sum_{\lambda=0}^{l-1} p^{k-k} q^{l-\lambda_{u}} u_{\kappa \cdot \lambda}}
\end{aligned}
$$

( $u_{m n} \in D_{2} ; u_{m \lambda}, u_{k n}$ initial values; $k, \ell$ natural numbers; $p, q$ inverses to shift operators in $Q_{2}$ ), one obtains the operator representation

$$
\begin{equation*}
\mathrm{u}=\frac{\mathrm{h}(\mathrm{p}, \mathrm{q}, \mathrm{~m}, \mathrm{n})}{\mathrm{g}(\mathrm{p}, \mathrm{q})}, \tag{10}
\end{equation*}
$$

where the numerator is

$$
\mathrm{h}=\alpha_{\mathrm{n}} \mathrm{~h}_{1}+\gamma_{\mathrm{m}} \mathrm{~h}_{2}+\beta_{\mathrm{n}} \mathrm{~h}_{3}+\delta_{\mathrm{m}} \mathrm{~h}_{4}+\alpha_{0} \mathrm{~h}_{5}+\alpha_{1} \mathrm{~h}_{6}+\beta_{0} \mathrm{~h}_{7}+\beta_{1} \mathrm{~h}_{8},
$$

as one can easily verify with the polynomials

$$
\begin{aligned}
& h_{1}(p, q)=p^{2} q^{2}-p q^{2}-p^{2} q+3 p q-p^{2}, \quad h_{2}=h_{1}(q, p), \\
& h_{3}(p, q)=p q^{2}-p q-p, \quad h_{4}=h_{3}(q, p), \quad h_{5}=-p^{2} q^{2}+p q^{2}+p^{2} q-3 p q, \\
& h_{6}(p, q)=-p^{2} q+p q, \quad h_{7}=h_{6}(q, p), \quad h_{8}=-p q
\end{aligned}
$$

and the coefficients, the given initial values,

$$
\begin{align*}
& \alpha_{\mathrm{n}}=\mathrm{u}_{0 \mathrm{n}}, \gamma_{\mathrm{m}}=\mathrm{u}_{\mathrm{m} 0}, \beta_{\mathrm{n}}=\mathrm{u}_{\mathrm{m}}, \delta_{\mathrm{m}}=\mathrm{u}_{\mathrm{m}_{1}} \quad \text { with }  \tag{11}\\
& \alpha_{0}=\gamma_{0}, \beta_{0}=\gamma_{1}, \alpha_{1}=\delta_{0}, \beta_{1}=\delta_{1} .
\end{align*}
$$

The denominator, a polynomial of degree 4 in $p, q$ is

$$
\mathrm{g}(\mathrm{p}, \mathrm{q})=\mathrm{p}^{2} \mathrm{q}^{2}-\mathrm{pq}^{2}-\mathrm{p}^{2} \mathrm{q}+3 \mathrm{pq}-\mathrm{p}^{2}-\mathrm{q}^{2}=\mathrm{g}_{1}(\mathrm{p}, \mathrm{q}) \mathrm{g}_{2}(\mathrm{p}, q)
$$

with

$$
\mathrm{g}_{1}=\mathrm{pq}-\alpha \mathrm{p}-\beta \mathrm{q} \quad \text { and } \quad \mathrm{g}_{2}=\mathrm{pq}-\beta \mathrm{p}-\alpha \mathrm{q},
$$

where $\alpha$ and $\beta$ have the values given in (8). As can be immediately proved,

$$
\frac{\mathrm{h}_{\mathrm{i}}}{\mathrm{~g}(\mathrm{p}, \mathrm{q})} \in \mathrm{D}_{2}
$$

holds for $i=1, \cdots, 8$; and these terms are indeed functions of the Fibonacci numbers $F_{k}$ 。 If considerations for the operator

$$
\frac{p^{2} q^{2}}{g(p, q)}
$$

are indicated, the calculation for the remaining members of $u_{m n}$ then follows easily. If one conceives

$$
\frac{\mathrm{pq}^{2}}{\mathrm{~g}(\mathrm{p}, \mathrm{q})}
$$

as a (proper fractional) rational operator of $p$ alone, then there results, by decomposition into partial fractions,

$$
\frac{p^{2} q^{2}}{g(p, q)}=\frac{1}{\alpha-\beta}\left(\frac{\alpha p q}{g_{2}(p, q)}-\frac{\beta p q}{g_{1}(p, q)}\right) \frac{q}{q-1}
$$

and on account of the obvious relations

$$
\frac{\mathrm{pq}}{\mathrm{~g}_{2}(\mathrm{p}, \mathrm{q})}=\binom{\mathrm{m}+\mathrm{n}}{\mathrm{~m}} \alpha^{\mathrm{m}_{\beta} \mathrm{n}}, \quad \frac{\mathrm{pq}}{\mathrm{~g}_{1}(\mathrm{p}, \mathrm{q})}=\binom{\mathrm{m}+\mathrm{n}}{\mathrm{~m}} \alpha^{\mathrm{n}_{\beta} \mathrm{m}}
$$

and of the meaning of $q /(q-1)$ as a "partial summation operator"

$$
\frac{\mathrm{q}}{\mathrm{q}-1} \mathrm{~b}_{\mathrm{mn}}=\sum_{\nu=0}^{\mathrm{n}} \mathrm{~b}_{\mathrm{m} \nu}
$$

it follows that

$$
\frac{p^{2} q^{2}}{g(p, q)}=\frac{1}{\alpha-\beta} \sum_{k=0}^{n}\binom{m+k}{m}\left[\alpha^{m+1} \beta^{k}-\alpha^{k} \beta^{m+1}\right]
$$

from which, on account of $\alpha^{\mathrm{k}} \beta^{\mathrm{k}}=(-1)^{\mathrm{k}}$ (k integral), of definition (8), of the symmetry of $g(p, q)$, and with the notation $G_{m n}$ for $\left(p^{2} q^{2}\right) / g$, there finally results
(12) $\frac{\mathrm{p}^{2} \mathrm{q}^{2}}{\mathrm{~g}(\mathrm{p}, \mathrm{q})}=G_{\mathrm{mn}}=G_{\mathrm{nm}}=\sum_{\mathrm{k}=0}^{\mathrm{n}}(-1)^{\mathrm{k}}\binom{\mathrm{m}+\mathrm{k}}{\mathrm{k}} \mathrm{F}_{\mathrm{m}+1-\mathrm{k}}=$

$$
\sum_{k=0}^{m}(-1)^{k}\binom{n+k}{k} F_{n+1-k} \quad \text { for } m, n \geq 0
$$

With the aid of (12) the operators $h_{i} / g(i=1, \cdots, 8)$ can now be immediately
represented as functions from $D_{2}$. In order to simplify the notation, we define $G_{m n}=0$ in case an index is negative; according to (12) this is also achieved by stipulating the following:

$$
\begin{equation*}
\sum_{k=0}^{\ell} a_{k}=0,\binom{\ell}{k}=0 \quad \text { for } \ell<0 \tag{13}
\end{equation*}
$$

(With this agreement, $\left(1 / p^{2}\right) G_{m n}=G_{m-2, n}$, for example, holds for all $m, n$ $\geq 0$.)
Therewith we obtain, after easy calculation from (10),
(14) $u_{m n}=\alpha_{n} \cdot\left(1+G_{m-2, n}\right)+\gamma_{m} \cdot\left(1+G_{m, n-2}\right)$

$$
\begin{aligned}
& +\beta_{n} \cdot\left(G_{m-1, n}-G_{m-1, n-1}-G_{m-1, n-2}\right) \\
& +\delta_{m} \cdot\left(G_{m, n-1}-G_{m-1, n-1}-G_{m-2, n-1}\right)-\alpha_{0} G_{m n} \\
& +\left(\alpha_{0}-\beta_{0}\right) G_{m-1, n}+\left(\alpha_{0}-\alpha_{1}\right) G_{m, n-1}-\left(3 \alpha_{0}-\beta_{0}-\alpha_{1}+\beta_{1}\right) G_{m-1, n-1} \\
& \quad \text { for all } m, n \geq 0 .
\end{aligned}
$$

(In this the multiplication symbol means multiplication in $D_{2}$ and the summand 1 is the identity element of $D_{2}$. ) If we finally use

$$
G_{m-1, n}-G_{m-1, n-1}=(-1)^{n}\binom{m+n-1}{n} F_{m-n}
$$

and correspondingly

$$
G_{m, n-1}-G_{m-1, n-1}=(-1)^{m}\binom{m+n-1}{m} F_{n-m} \quad \text { for } m, n \geq 0
$$

and carry out the multiplication in $D_{2}$ then after simple transformations for $\mathrm{m}, \mathrm{n} \geq 0$ we obtain from (14)
(15) $u_{m n}=\alpha_{n}+\gamma_{m}+\sum_{\nu=0}^{n} G_{m-2, \nu} \alpha_{n-\nu}+\sum_{\mu=0}^{m} G_{\mu, n-2 \gamma m-\mu}$

$$
\begin{aligned}
& +\sum_{\nu=0}^{\mathrm{n}}(-1)^{\nu}\binom{\mathrm{m}+\nu-1}{\nu} \mathrm{~F}_{\mathrm{m}-\nu} \beta_{\mathrm{n}-\nu}-\sum_{\nu=0}^{\mathrm{m}} \mathrm{G}_{\mathrm{m}-1, \nu-2} \beta_{\mathrm{n}-\nu} \\
& +\sum_{\mu=0}^{\mathrm{m}}(-1)^{\mu}\binom{\mathrm{n}+\mu-1}{\mu} \mathrm{~F}_{\mathrm{n}-\mu} \delta_{\mathrm{m}-\mu}-\sum_{\mu=0}^{\mathrm{m}} \mathrm{G}_{\mu-2, \mathrm{n}-1} \delta_{\mathrm{m}-\mu} \\
& -\alpha_{0}(-1)^{\mathrm{m}}\binom{\mathrm{~m}+\mathrm{n}}{\mathrm{~m}} \mathrm{~F}_{\mathrm{n}-\mathrm{m}+1}-\beta_{0}(-1)^{\mathrm{n}}\binom{\mathrm{~m}+\mathrm{n}-1}{\mathrm{n}} \mathrm{~F}_{\mathrm{m}-\mathrm{n}} \\
& +\left(\alpha_{0}-\alpha_{1}\right)(-1)^{\mathrm{m}}\binom{\mathrm{~m}+\mathrm{n}-1}{\mathrm{~m}} \mathrm{~F}_{\mathrm{n}-\mathrm{m}}-\left(2 \alpha_{0}+\beta_{1}\right) \mathrm{G}_{\mathrm{m}-1, \mathrm{n}-1} .
\end{aligned}
$$

We verify that (15) satisfies equation ( $1^{1}$ ), however, we only indicate the calculation: to begin with, $\mathrm{D}\left(\alpha_{\mathrm{n}}\right)=-\alpha_{\mathrm{n}+2}$ holds and $\mathrm{D}\left(\gamma_{\mathrm{m}}\right)=-\gamma_{\mathrm{m}+2}$.

Furthermore,

$$
\begin{aligned}
& \mathrm{D}\left(\sum_{\nu=0}^{\mathrm{n}} \mathrm{G}_{\mathrm{m}-2, \nu} \alpha_{\mathrm{n}-\nu}\right)= \sum_{\nu=2}^{\mathrm{n}+2} \alpha_{\mathrm{n}+2-\nu} \mathrm{D}\left(\mathrm{G}_{\mathrm{m}-2, \nu-2}\right)+\mathrm{n}-\alpha_{\mathrm{n}+2}\left[\mathrm{G}_{\mathrm{m} 0}-\mathrm{G}_{\mathrm{m}-1,0}-\mathrm{G}_{\mathrm{m}-2,0}\right] \\
&+\alpha_{\mathrm{n}+1}\left[\mathrm{G}_{\mathrm{m} 1}-\mathrm{G}_{\mathrm{m}-1,1}-\mathrm{G}_{\mathrm{m} 0}-\mathrm{G}_{\mathrm{m}-2,1}+3 \mathrm{G}_{\mathrm{m}-1,0}\right] \\
&=\alpha_{\mathrm{n}+2}
\end{aligned}
$$

for, it is true that $G_{m 0}-G_{m-1,0}-G_{m-2,0}=\left\{\begin{array}{l}1 \text { for } m=0, \\ 0 \text { for } m>0,\end{array}\right.$

$$
G_{m 1}-G_{m-1,1}-G_{m 0}-G_{m-2,1}+3 G_{m-1,0}=0 \text { for all } m \geq 0
$$

and

$$
\mathrm{D}\left(\mathrm{G}_{\mathrm{m}-2, \nu-2}\right)=0 \text { for } \mathrm{m} \geq 0, \quad \nu \geq 2
$$

as one recognizes after some calculation with the aid of (12) and $F_{k}=(-1)^{k+1} F_{-k}$ ( $k$ integral) or as one can read off directly from the fact that $G_{m n}$ in $D_{2}$ is inverse to

$$
\frac{\mathrm{g}}{\mathrm{p}^{2} \mathrm{q}^{2}}=1-\frac{1}{\mathrm{p}}-\frac{1}{\mathrm{q}}-\frac{1}{\mathrm{q}^{2}}+\frac{3}{\mathrm{pq}}-\frac{1}{\mathrm{p}^{2}}=\left(\begin{array}{rrrlll}
1 & -1 & -1 & 0 & 0 & \cdots \\
-1 & 3 & 0 & 0 & \cdots \\
-1 & 0 & 0 & \cdots & \\
0 & 0 & \cdots &
\end{array}\right)
$$

by (9).
Analogously one completes the verification. By appropriate calculation one recognizes that the initial conditions (11) are satisfied by (15). Since $\delta_{0}=\alpha_{1}$, and because of definition (13) and of the validity of the relation (3) for $F_{n}$, there results for $m=0, n \geq 0$, for instance,

$$
\mathrm{u}_{0 \mathrm{n}}=\alpha_{\mathrm{n}}+{ }_{0}+\mathrm{G}_{0, \mathrm{n}-20}+\binom{\mathrm{n}-1}{0} \mathrm{~F}_{\mathrm{n} 0}-\alpha_{0} \mathrm{~F}_{\mathrm{n}+1}+\left(\alpha_{0}-\alpha_{1}\right)\binom{\mathrm{n}-1}{0} \mathrm{~F}_{\mathrm{n}}=\alpha_{\mathrm{n}}
$$

## RECURRING SEQUENCES

Review of Book by Dov Jarden By Brother Alfred Brousseau

For some time the volume, Recurring Sequences, by Dov Jarden has been unavailable, but now a printing has been made of a revised version. The new book contains articles published by the author on Fibonacci rumbers and related matters in Riveon Lematematika and other publications. A number of these articles were originally in Hebrew and hence unavailable to the general reading public. This volume now enables the reader to become acquainted with this extensive material (some thirty articles) in convenient form.

In addition, there is a list of Fibonacci and Lucas numbers as well as their known factorizations up to the 385th number in each case. Many new results in this section are the work of John Brillhart of the University of San Francisco and the University of California.

There is likewise, a Fibonacci bibliography which has been extended to include articles to the year 1962.

This valuable reference for Fibonacci fanciers is now available through the Fibonacci Association for the price of $\$ 6.00$. All requests for the volume should be sent to Brother Alfred Brousseau, Managing Editor, St. Mary's College, Calif., 94575.

The Fibonacci Association invites Educational Institutions to apply for Academic Membership in the Association. The minimum subscription fee is $\$ 25$ annually. (Academic Members will receive two copies of each issue and will have their names listed in the Journal.

# ENUMERATION OF PARTITIONS SUBJECT TO LIMITATIONS ON SIZE OF MEMBERS 

Daniel C. Fielder, Georgia Institute of Technology, Atlanta, Georgia

## 1. INTRODUCTION

In a previous work [1], it was shown that the partition enumeration* $\mathrm{P}(\mathrm{n}|\mathrm{p}| \leq \mathrm{n}+\mathrm{p}-1)$ is given by

$$
\begin{array}{cc}
P(n|p| \leq n+p-1)=\left[\frac{n-p+2}{2}\right]+\sum_{i=1}\left[\frac{n-p+2-w_{i}}{2}\right] & p \neq 1,  \tag{1}\\
P(n|p| \leq n+p-1)=1 & p=1 .
\end{array}
$$

The $w_{i}$ are the sums of each partition in the set of partitions described by $\operatorname{PV}(\geq 3, \leq \mathrm{n}-\mathrm{p}|\geq 1, \leq[(\mathrm{n}-\mathrm{p}) / 3]| \geq 3, \leq \mathrm{p})$. It was stated in [1] that the summation term of (1) is zero for those values of $p$ and ( $n-p$ ) for which $P V(\geqslant 3$, $\leq n-p|\geq 1, \leq[(n-p) / 3]| \geq 3, \leq p$ ) does not exist. (See the footnote below for a brief description of nomenclature.) For $n-p<3$ and/or $p=2, w_{i}=0$. One raison d'être for (1) is the adaptability of $w_{i}$ to digital computation.
$P(n|p| \leq n-p+1)$ is a basic enumeration form which is extremely useful in evaluating more restrictive enumerations [2]. $\mathrm{PV}(\mathrm{n}|\mathrm{p}| \leq n-\mathrm{p}+1)$ shares this versatility in that sets of many other partition types can be constructed by operations on the members of the partitions of the basic set. When $\operatorname{PV}(\mathrm{n}|\mathrm{p}| \leq n$ $-p+1$ ) is under consideration, it is convenient to arrange the $p$ members of a partition so that

$$
\begin{equation*}
a_{p} \leq a_{p-1} \leq a_{p-2} \leq \cdots \leq a_{2} \leq a_{1} \tag{2}
\end{equation*}
$$

$P(n|p| \leq q)$ is the enumeration of the partitions of $n$ into exactly $p$ members, no member of which is greater than $q$. The appended notation $P V(n|p| \leq q)$ is the actual set of such partitions. The use of $\geq$ and/or $\leq$ symbols with $n$, p, or $q$ defines lower limits and/or upper limits of the quantity modified. Note that [] (except for obvious reference use) is used with realnumbers to indicate the greatest integer less than or equal to the number bracketed.
where $a_{k}$ is an individual partition member. The arrangement of (2) leads to an initial partition of $P V(n|p| \leq n-p+1)$ as

$$
\begin{array}{c|c|c|c|c|c}
a_{p} & a_{p-1} & a_{p-2} & \cdots & a_{2} & a_{1}  \tag{3}\\
\hline 1 & 1 & 1 & \cdots & 1 & n-p+1
\end{array}
$$

One method [3] of generating successive partitions of $\operatorname{PV}(\mathrm{n}|\mathrm{p}| \leq n-p+1)$ starts with (3) and successively increases $a_{2}$ by 1 and decreases $a_{1}$ by 1 until (2) is just barely satisfied. New members, $a_{p}, a_{p-1}, \cdots, a_{2}, a_{1}$ are chosen exhaustively, and the increase $a_{2}$-decrease $a_{1}$ process is repeated.

Based on the above brief background, it is possible to consider the following enumeration extensions to (1):
(a) $\quad P(n|p| \geq s)$. No member less than $s$, where $s$ is a positive integer such that $\mathrm{s} \leq \mathrm{n}-\mathrm{p}+1$.
(b) $P(n|p| \leq r)$. No member greater than $r$ where $r$ is a positive integer such that $r \leq n-p+1$.
(c) $P(n|p| \geq s, \leq r)$. No member less than $s$, or greater than $r$.

## 2. ENUMERATION OF $\mathrm{P}(\mathrm{n}|\mathrm{p}| \geq \mathrm{s})$

There exists one member of a partition in the set $\operatorname{PV}(\mathrm{n}|\mathrm{p}| \geq \mathrm{s})$ which is at least as large as any member of any partition in the set. Let this member be $q_{S}$ which can readily be found as

$$
\begin{equation*}
q_{S}=n-s(p-1) \tag{4}
\end{equation*}
$$

This implies that for any $a_{1}$,

$$
\begin{equation*}
\mathrm{n}-\mathrm{ps}+\mathrm{s} \geq \mathrm{a}_{1} \geq \mathrm{s} \tag{5}
\end{equation*}
$$

from which a necessary condition of $P(n|p| \geq s)$ is seen to be

$$
\begin{equation*}
\left(\frac{\mathrm{n}}{\mathrm{p}}\right) \geq \mathrm{s} \tag{6}
\end{equation*}
$$

The initial partition of $\operatorname{PV}(n|p| \geq s)$ is

$$
\begin{equation*}
s, s, s, \cdots, s, n-s(p-1) \tag{7}
\end{equation*}
$$

If $s-1$ is subtracted from each member of (7), the result is a modified initial partition

$$
\begin{equation*}
1,1,1, \cdots, 1, \mathrm{n}-\mathrm{sp}+1 \tag{8}
\end{equation*}
$$

The complete enumeration for a partition set starting with (8) is, according to (1), $P\left(n^{\prime}|p| \leq n^{\prime}-p+1\right)$, where

$$
\begin{equation*}
\mathrm{n}^{\prime}=\mathrm{n}-\mathrm{sp}+\mathrm{p} \tag{9}
\end{equation*}
$$

Because the $a_{1}$ and $a_{2}$ members of the initial partitions (7) and (8) differ by the same integer ( $n-s p$ ) and because each $a_{k}$ of each partition developed from (7) is ( $s-1$ ) greater than the corresponding $a_{k}$ of the corresponding partition developed from (8), there are exactly as many partitions developable from the start of (7) as there are from (8). Hence, $P(n|p| \geq s)$ appears in the form of (1) as

$$
\begin{equation*}
P(n|p| \geq s)=P\left(n^{p} \mid p \| \leq n^{\prime}-p+1\right) \tag{10}
\end{equation*}
$$

As a simple example, consider $P(15|6| \geq 2)$. For this case, $n=15$, and $n^{\prime}=$ 9. It is seen below that $P(15|6| \geq 2)=P(9|6| \leq 4)=3$.

$$
\begin{array}{ll}
\frac{P V(15|6| \geq 2)}{2,2,2,2,2,5} & \frac{P V(9|6| \leq 4)}{1,1,1,1,1,4} \\
2,2,2,2,3,4 & 1,1,1,1,2,3 \\
2,2,2,3,3,3 & 1,1,1,2,2,2
\end{array}
$$

## 3. ENUMERATION OF $P(n|p| \leq r)$

The partitions of the set $\operatorname{PV}(\geq 3, \leq n-p|\geq 1, \leq[(n-p) / 3]| \geq 3 \leq p)$ can be arranged in columns according to the number of members in a partition. This is illustrated in Table 1 for $n=16, p=5$.

| $\mathbf{i}$ | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
|  | 0 | 3 | 3,3 | $3,3,3$ |
| $\mathrm{PV}(\geq 3, \leq 11\|\geq 1, \leq 3\| \geq 3, \leq 5)$ |  | 4 | 3,4 | $3,3,4$ |
|  |  | 5 | 3,5 | $3,3,5$ |
|  |  |  | 4,4 | $3,4,4$ |
|  |  |  | 4,5 |  |

Table 1
The sum of members of each partition is equal to a $w_{i}$ for use in (1). The use of the index $i$ can be extended somewhat to allow it to designate the column from which the summed partition was taken. Although $w_{i}$ might stand for any of several sums, no loss in generality results thereby since all of these sums must eventually be considered. To account for the non-summation term in (1), a zero $^{\text {th }}$ column with a lone zero entry is added to indicate that an added $\mathrm{w}_{0}=$ 0 . Table 2 shows values of $\mathrm{w}_{\mathrm{i}}$ for $\mathrm{n}=16, \mathrm{p}=5$.

| i | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
|  | 0 | 3 | 6 | 9 |
|  |  | 4 | 7 | 10 |
|  |  | 5 | 8 | 11 |
|  |  |  | 8 | 11 |
|  |  |  | 9 |  |
|  |  |  | 10 |  |

Table 2 Values of $w_{i}$
If, as the $w_{i}$ 's are successively selected for enumerating $P(n|p| \leq n-p$ $+1)$ in (1), a simultaneous generation of the partitions in the set $P V(n|p| \leq n-$ $p+1$ ) is made (by the increase $a_{2}$-decrease $a_{1}$ method, for example) there would result subsets of $\operatorname{PV}(n|p| \leq n-p+1)$ each having [ $\left.\left.n-p+2-w_{i}\right) / 2\right]$ partitions of $n_{\text {。 }}$ For $i=0$, the subset can easily be constructed. It is seen that the $a_{2}$ and $a_{3}$ members of the initial partition must necessarily be one. For $i=1$, the $a_{2}$ and $a_{3}$ members of the initial partition assume the least
possible value two since $i=0$ has accounted for the value one. It can be argued in this fashion that the $a_{2}$ and $a_{3}$ members of an initial partition in a subset must be $(i+1)$. The $a_{1}$ member of the initial partition of the subset would not generally be known in advance. However, this member is certainly not less than any member of any partition in the subset. Set $d_{i}$ be the $a_{1}$ member of the initial partition corresponding to the particular $w_{i}$. If $b_{i}$ are the number of partitions in the subset, the bracketed terms of (1) limit the possibilities of $b_{i}$ to either

$$
\begin{equation*}
n-p+1-w_{i}=2 b_{i}-1 \tag{11}
\end{equation*}
$$

or

$$
\begin{equation*}
n-p+1-w_{i}=2 b_{i} \tag{11a}
\end{equation*}
$$

The arrangement of the subset of $b_{i}$ partitions is

From (12), it can be deduced that either

$$
\begin{equation*}
\mathrm{d}_{\mathrm{i}}=2 \mathrm{~b}_{\mathrm{i}}-1+\mathrm{i} \tag{13}
\end{equation*}
$$

or
(13a)

$$
d_{i}=2 b_{i}+i
$$

Comparison of (13) with (11) and (13a) with (11a) yields the desired

$$
\begin{equation*}
\mathrm{d}_{\mathbf{i}}=\left(\mathrm{n}-\mathrm{p}+1-\mathrm{w}_{\mathrm{i}}+\mathrm{i}\right) \tag{14}
\end{equation*}
$$

An illustration is given in Table 3 for construction of $\operatorname{PV}(16|5| \leq 12)$, consistent with the $\mathrm{w}_{\mathrm{i}}$ from $\mathrm{PV}(\geq 3, \leq 11|\geq 1, \leq 3| \geq 3, \leq 5)$ as arranged in Tables 1 and 2.

Table $3 \operatorname{PV}(16|5| \leq 12)$

Table 4 shows $b_{i}$ corresponding to $w_{i}$ of Table 1 for $P(16|5| \leq 12)=\sum_{i=0} b_{i}$.

| i | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
|  | 6 | 5 | 3 | 2 |
|  |  | 4 | 3 | 1 |
| $\mathrm{~b}_{\mathrm{i}}$ |  | 4 | 2 | 1 |
|  |  |  | 2 | 1 |
|  |  |  | 1 |  |

Table $4 \sum_{i} b_{i}=P(16|5| \leq 12)=37$

Let the $b_{i}$ for $P(n|p| \leq r)$ be $b_{i r}$. It follows that for $P(n|p| \leq r)$ each $b_{i r}$ can have no more (and will possibly have less) than $b_{i}$ partitions. The non-negative integer by which $b_{i r}$ is less than $b_{r}$ can be observed by comparing $r$ with the entries in the $a_{1}$ column of (12). This leads immediately to

$$
\begin{equation*}
P(n|p| \leq r)=\left[\frac{n-p+2}{2}\right]-\alpha_{0}+\sum_{i=1}\left(\left[\frac{n-p+2-w_{i}}{2}\right]-\alpha_{1}\right)=\sum_{i=0} b_{i r} \tag{15}
\end{equation*}
$$

where

$$
\alpha_{1}=\left\{\begin{array}{cl}
0 & \left(r \geq d_{i}\right)  \tag{16}\\
d_{i}-r & \left(d_{i}>r \geq\left(d_{i}-b_{i}+1\right)\right) \\
{\left[\frac{n-p+2-w_{i}}{2}\right]} & \left(r<\left(d_{i}-b_{i}+1\right)\right)
\end{array}\right.
$$

Table 5 serves to illustrate (15) for $\mathrm{n}=16, \mathrm{p}=5, \mathrm{r}=7$ 。

| i | 0 | 1 | 2 | 3 |
| :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 2 | 2 |
| $\mathrm{~b}_{\mathrm{ir}}$ |  | 2 | 3 | 1 |
|  |  | 3 | 2 | 1 |
|  |  |  | 2 | 1 |
|  |  |  | 1 |  |

Table $5 \sum_{\mathrm{i}} \mathrm{b}_{\mathrm{ir}}=\mathrm{P}(16|5| \leq 7)=23$

## 4. ENUMERATION OF $P(n|p| \geq s, \leq r)$

The combination of the previous two methods leads quickly to the desired enumeration. Reference to (10) reveals a $P\left(n^{\prime}|p| \leq n^{\prime}-p+1\right)$ for whichevery member of each partition of $\operatorname{PV}\left(n^{\prime}|p| \leq n^{\prime}-p+1\right)$ is ( $s-1$ ) less than the corresponding member of the appropriate counterpart in $P V(n|p| \geq s)$. If the desired $r$ is depressed to $r^{\prime}$ where

$$
r^{\prime}=r-(s-1)
$$

the enumeration $P\left(n_{j}|p| \geq_{s}, \leq r\right)$ is equal to $P\left(n^{\prime}|p| \leq r^{\prime}\right)$.

DID YOU KNOW?

Prof. D. E. Knuth of California Institute of Technology is working on a 3volume book, The Analysis of Algorithms, which has 39 exercises at the end of the section which introduces the Fibonacci Sequence. However, the Fibonacci Sequence occurs in many different places, both as an operational tool, or to serve as examples of good sequences and also bad sequences. He reports that there are at least 12 different algorithms directly or indirectly connected with the Fibonacci Sequence. In the age of computers, the Fibonacci Sequence is coming of age in many ways. This book will be a most welcome addition to the growing list of Fibonacci related books and articles.

Prof. C. T. Long of Washington State University has written a very nice book, Elementary Introduction to Number Theory, 1965, Heath, Boston. It contains a good discussion of the Fibonacci Numbers in Chapter One and several Fibonacci Problems in Chapters I and II.

# ON THE DIVISIBILITY PROPERTIES OF FIBONACCI NUMBERS 

John H. Halton, University of Colorado, Boulder, Colorado

## 1. INTRODUCTION

The Fibonacci sequence is defined by the recurrence relation
(1)

$$
\mathrm{F}_{\mathrm{n}+2}=\mathrm{F}_{\mathrm{n}+1}+\mathrm{F}_{\mathrm{n}}
$$

together with the particular values
$\left\{\begin{array}{l}\mathrm{F}_{0}=0, \mathrm{~F}_{1}=1, \\ \text { whence } \\ \mathrm{F}_{2}=1, \mathrm{~F}_{3}=2, \mathrm{~F}_{4}=3, \mathrm{~F}_{5}=5, \mathrm{~F}_{6}=8=2^{3}, \mathrm{~F}_{7}=13 \\ \mathrm{~F}_{8}=21=3 \cdot 7, \mathrm{~F}_{9}=34=2 \cdot 17, \mathrm{~F}_{10}=55=5 \cdot 11, \cdots, \\ \text { and, in particular, } \\ \mathrm{F}_{12}=144=2^{4} \cdot 3^{2}, \mathrm{~F}_{14}=377=13 \cdot 29, \mathrm{~F}_{15}=610=2 \cdot 5 \cdot 61, \\ \mathrm{~F}_{18}=2584=2^{3} \cdot 17 \cdot 19, \mathrm{~F}_{20}=6765=3 \cdot 5 \cdot 11 \cdot 41, \\ \mathrm{~F}_{21}=10946=2 \cdot 13 \cdot 421, \mathrm{~F}_{24}=46368=2^{5 \cdot} 3^{2} \cdot 7 \cdot 23, \\ \mathrm{~F}_{25}=75025=5^{2} \cdot 3001, \mathrm{~F}_{28}=317811=3 \cdot 13 \cdot 29 \cdot 281, \\ \mathrm{~F}_{30}=832040=2^{3} \cdot 5 \cdot 11 \cdot 31 \cdot 61, \mathrm{~F}_{35}=9227465=5 \cdot 13 \cdot 141961, \\ \mathrm{~F}_{36}=14930352=24 \cdot 3^{3} \cdot 17 \cdot 19 \cdot 107, \mathrm{~F}_{42}=267914296=2^{3} \cdot 13 \cdot 29 \cdot 211 \cdot 421 \\ \mathrm{~F}_{70}=190392490709135=5 \cdot 11 \cdot 13 \cdot 29 \cdot 71 \cdot 911 \cdot 141961\end{array}\right.$

In this paper, we shall be concerned with the sub-sequence of Fibonacci numbers which are divisible by powers of a given integer. We shall also be interested in the associated problem of the periodic nature of the sequence of remainders, when the Fibonacci numbers are divided by a given integer.

The Fibonacci sequence is defined for all integer values of the index $n$. However, the well-known identity

$$
\begin{equation*}
\mathrm{F}_{-\mathrm{n}}=(-1)^{\mathrm{n}+1} \mathrm{~F}_{\mathrm{n}} \tag{3}
\end{equation*}
$$

shows that negative indices add nothing to the divisibility properties of the Fibonacci numbers. We shall consequently simplify our discussion, without loss of generality, by imposing the restriction that $n \geq 0$.

Of the many papers dealing with our problem, perhaps the most useful are those of Carmichael [1], Robinson [5], Vinson [6], and Wall [7]; and the reader can find many additional references in these. Most of the other papers in the field give either less complete results, or give them for more general sequences.

We shall make use, in what follows, of the well-known identities:*

$$
\begin{gather*}
\mathrm{F}_{\mathrm{n}}=\frac{1}{\sqrt{5}}\left\{\left(\frac{1+\sqrt{5}}{2}\right)^{\mathrm{n}}-\left(\frac{1-\sqrt{5}}{2}\right)^{\mathrm{n}}\right\} ;  \tag{4}\\
\mathrm{F}_{\mathrm{n}}=\left(\frac{1}{2}\right)^{\mathrm{n}-1} \sum_{\mathrm{S}=0}^{\left[\frac{1}{2}(\mathrm{n}-1)\right]}\binom{\mathrm{n}}{2 \mathrm{~s}+1} 5^{\mathrm{s}}, \text { if } \mathrm{n} \geq 1 \tag{5}
\end{gather*}
$$

$$
\begin{equation*}
\mathrm{F}_{\mathrm{n}}^{2}-\mathrm{F}_{\mathrm{n}-1} \mathrm{~F}_{\mathrm{n}+1}=(-1)^{\mathrm{n}-1} \tag{6}
\end{equation*}
$$

$$
F_{k n+r}=\sum_{h=0}^{k}\binom{k}{n} F_{n}^{h} F_{n-1}^{k-h} F_{r+h}, \quad \text { if } k \geq 0
$$

and since $F_{0}=0$,

$$
\begin{equation*}
\mathrm{F}_{\mathrm{kn}}=\mathrm{F}_{\mathrm{n}} \sum_{\mathrm{h}=1}^{\mathrm{k}}\binom{\mathrm{k}}{\mathrm{~h}} \mathrm{~F}_{\mathrm{n}}^{\mathrm{h}-1} \mathrm{~F}_{\mathrm{n}-1}^{\mathrm{k}-\mathrm{h}} \mathrm{~F}_{\mathrm{h}} \tag{8}
\end{equation*}
$$

*See, for example, equations (6), (3), (5), (67), and (34), in my earlier + paper [3]. Equation (5) above follows from (4) by the binomial theorem.

Also
(9)

$$
\binom{k+1}{h}=\binom{k}{h}+\binom{k}{h-1}
$$

and

$$
\begin{equation*}
\mathrm{p} \text { divides }\binom{\mathrm{p}}{\mathrm{~s}} \text { if } \mathrm{p} \text { is prime and } 0<\mathrm{s}<\mathrm{p} \tag{10}
\end{equation*}
$$

and Fermat's theorem, that

$$
\begin{equation*}
\mathrm{m}^{\mathrm{p}-1} \equiv 1(\bmod \mathrm{p}) \text { if } \mathrm{p} \text { is prime and }(\mathrm{m}, \mathrm{p})=1 \tag{11}
\end{equation*}
$$

As is customary, we use ( $A, B, C, \cdots$ ) to represent the greatest common factor of integers $A, B, C, \cdots$, and $[A, B, C, \cdots]$ to represent their least common multiple. We have

$$
\begin{equation*}
\mathrm{m}^{\frac{1}{2}(\mathrm{p}-1)} \equiv(\mathrm{m} / \mathrm{p})(\bmod \mathrm{p}) \tag{12}
\end{equation*}
$$

where $p$ is an odd prime and ( $\mathrm{m} / \mathrm{p}$ ) denotes the Legendre index, which is $\pm 1$ if $(\mathrm{m}, \mathrm{p})=1$, and 0 otherwise.

Each writer seems to have invented his own notation. I shall adopt the following, which comes closest to that of Robinson in [5].

Definition 1. The least positive index $a$ such that $F_{\alpha}$ is divisible by $\mathrm{m}^{\mathrm{n}}$ (that is, $\mathrm{F}_{\alpha} \equiv 0\left(\bmod \mathrm{~m}^{\mathrm{n}}\right)$ ) will be written

$$
\begin{equation*}
\alpha(\mathrm{m}, \mathrm{n})=\alpha\left(\mathrm{m}^{\mathrm{n}}, 1\right)=\alpha\left(\mathrm{m}^{\mathrm{n}}\right) \tag{13}
\end{equation*}
$$

This is variously called the "rank of apparition" (why not "appearance"?) of $\mathrm{m}^{\mathrm{n}}$, or the "restricted period" of the Fibonacci sequence modulo $\mathrm{m}^{\mathrm{n}}$.

Definition 2. The least positive index $\mu$ such that both $\mathrm{F}_{\mu} \equiv 0$ and $\mathrm{F}_{\mu+1} \equiv 1\left(\bmod \mathrm{~m}^{\mathrm{n}}\right)$ will be written

$$
\begin{equation*}
\mu(\mathrm{m}, \mathrm{n})=\mu\left(\mathrm{m}^{\mathrm{n}}, 1\right)=\mu\left(\mathrm{m}^{\mathrm{n}}\right) \tag{14}
\end{equation*}
$$

This notation follows Carmichael［2］，who named $\mu$ the＂characteristic number＂ of the Fibonacci sequence modulo $\mathrm{m}^{\mathrm{n}}$ 。 It is also called the＂period＂of the se－ quence modulo $\mathrm{m}^{\mathrm{n}}$ ．

Definition 3．I shall write

$$
\begin{equation*}
\mu(\mathrm{m}, \mathrm{n}) / \alpha(\mathrm{m}, \mathrm{n})=\beta(\mathrm{m}, \mathrm{n})=\beta\left(\mathrm{m}^{\mathrm{n}}, 1\right)=\beta\left(\mathrm{m}^{\mathrm{n}}\right) \tag{15}
\end{equation*}
$$

Definition 4。 The greatest integer $\nu$ such that $\mathrm{F}_{\alpha(\mathrm{m}, \mathrm{n})}$ is divisible by $\mathrm{m}^{\nu}$ will be written

$$
\begin{equation*}
\nu(\mathrm{m}, \mathrm{n})=\nu\left(\mathrm{m}^{\mathrm{n}}, 1\right)=\nu\left(\mathrm{m}^{\mathrm{n}}\right) \tag{16}
\end{equation*}
$$

It is then clear that
（17）$\alpha(\mathrm{m}, \mathrm{n})=\alpha(\mathrm{m}, \mathrm{n}+1)=\ldots=\alpha(\mathrm{m}, \nu(\mathrm{m}, \mathrm{n}))<\alpha(\mathrm{m}, \nu(\mathrm{m}, \mathrm{n})+1)$
or，equivalently，

$$
\begin{equation*}
\nu(\mathrm{m}, \nu(\mathrm{~m}, \mathrm{n}))=\nu(\mathrm{m}, \mathrm{n}) \tag{18}
\end{equation*}
$$

Definition 5．I shall call the sequence

$$
\begin{equation*}
F_{\alpha(m, 1)}, F_{\alpha(m, 2)}, \cdots, F_{\alpha(m, n)}, \cdots \tag{19}
\end{equation*}
$$

the divisibility sequence of m 。

## 2．PRELIMINARIES

We shall need a number of preliminary results，whose proofs will be out－ lined for completeness．

Lemma 1．$F_{n}, F_{n+1}$ ，and $F_{n+2}$ are always pairwise prime．
［If $f$ divides two of the numbers，it must divide the third，by（1）．Thus，，by
induction along the sequence，using（1），we see that $f$ must divide every $\mathrm{F}_{\mathrm{m}}$ 。 Thus，since $F_{1}=1, f=1$ ．］

Lemma 2．If $\mathrm{n} \geq 2, \mathrm{~F}_{\mathrm{n}}$ is a strictly increasing positive function of $\mathrm{n}_{\text {。 }}$ ［By（1），if $F_{n-2} \geq 0$ and $F_{n-1} \geq 1, F_{n+1}>F_{n} \geq 1$ 。By（2），$F_{0}=0$ and $\mathrm{F}_{1}=1$ ，whence the lemma follows by induction．］

Lemma 3．If $\mathrm{n} \geq 3$

$$
\begin{equation*}
\alpha\left(\mathrm{F}_{\mathrm{n}}\right)=\mathrm{n} \tag{20}
\end{equation*}
$$

［By Lemma 2，if $n \geq 3$ ，the least index $m$ such that $F_{m} \geq F_{n}$ is $n_{0}$ ］
Lemma 4。

$$
\begin{equation*}
\left(F_{m}, F_{n}\right)=F_{(m, n)} \tag{21}
\end{equation*}
$$

［Let $(\mathrm{m}, \mathrm{n})=\mathrm{g}$ and $\left(\mathrm{F}_{\mathrm{m}}, \mathrm{F}_{\mathrm{n}}\right)=\mathrm{G}$ 。 There are integers x and y （not both negative）such that $x m+y n=g$ ．Suppose $x \geq 0$ ；then，by（7），

$$
F_{g}=\sum_{h=0}^{x}\binom{x}{h} F_{m}^{h} F_{m-1}^{x-h} F_{y n+h} \equiv 0(\bmod G)
$$

since $G$ divides $F_{m}$ and $F_{n}$ ，and by（8），$F_{n}$ divides $F_{y n}$ ．Thus $F_{g}$ is divisible by $G$ ．Again，by（8）， $\mathrm{F}_{\mathrm{kg}} \equiv 0\left(\bmod \mathrm{~F}_{\mathrm{g}}\right)$ 。 Thus，since g divides both $m$ and $n, F_{g}$ divides both $F_{m}$ and $F_{n}$ ，and so $G$ is divisible by $\mathrm{F}_{\mathrm{g}}{ }^{\text {．}}$ ］

Lemma 5．$\quad \mathrm{F}_{\mathrm{m}}$ is divisible by $\mathrm{F}_{\mathrm{n}}$ ，if and only if either m is divisible by $n$ ，or $n=2$ 。
［By Lemma 4，$\left(\mathrm{F}_{\mathrm{m}}, \mathrm{F}_{\mathrm{n}}\right)=\mathrm{F}_{\mathrm{n}}$ if and only if $\mathrm{F}_{(\mathrm{m}, \mathrm{n})}=\mathrm{F}_{\mathrm{n}}$ ；that is，$(\mathrm{m}, \mathrm{n})=$ n or $\mathrm{n}=2$ 。］

Definition 6．The remainder when $\mathrm{F}_{\mathrm{n}}$ is divided by m will be written $\mathrm{F}_{\mathrm{n}}^{(\mathrm{m})}$ and will be called the residue of $\mathrm{F}_{\mathrm{n}}$ modulo m 。 Clearly

$$
\begin{equation*}
\mathrm{F}_{\mathrm{n}} \equiv \mathrm{~F}_{\mathrm{n}}^{(\mathrm{m})}(\bmod \mathrm{m}), \quad 0 \leq \mathrm{F}_{\mathrm{n}}^{(\mathrm{m})}<\mathrm{m} \tag{22}
\end{equation*}
$$

Lemma 6．The sequence of residues $\mathrm{F}_{\mathrm{n}}^{(\mathrm{m})}$ ，modulo any integer $\mathrm{m} \geq$ 2 ，is periodic with period $\mu(\mathrm{m})$ ．That is

$$
\begin{cases} & F_{n+k \mu(m)}^{(m)}=F_{n}^{(m)}  \tag{23}\\ \text { or } & F_{n+k \mu(m)} \equiv F_{n}(\bmod m)\end{cases}
$$

［ The ordered pair of integers $\mathrm{F}_{\mathrm{n}}^{(\mathrm{m})}, \mathrm{F}_{\mathrm{n}+1}^{(\mathrm{m})}$ can take at most $\mathrm{m}^{2}$ distinct val－ ues．Thus the $m^{2}+1$ such consecutive pairs in $F_{0}^{(m)}, F_{i}^{(m)}, \cdots, F_{m^{2}+1}^{(m)}$ must have a duplication．By backward induction on the indices of two equal pairs，using（1），we see that there must be a pair $\mathrm{F}_{\mathrm{k}}^{(\mathrm{m})}, \mathrm{F}_{\mathrm{k}+1}^{(\mathrm{m})}$ equal to $\mathrm{F}_{0}^{(\mathrm{m})}$ $=0, \mathrm{~F}_{1}^{(\mathrm{m})}=1$ ，with $2 \leq \mathrm{k} \leq \mathrm{m}^{2}$ 。By definition，the least such k is $\mu(\mathrm{m})$ ． The periodicity now follows from（1）．］

Lemma 7．For any integer $m$ ，we can find an $F_{n}$ divisible by $m$ ． ［For example， $\mathrm{n}=\mathrm{k} \mu(\mathrm{m})$ ，for any integer k ，by Lemma 6．］

Lemma 8． $\mathrm{F}_{\mathrm{n}}$ is divisible by m if and only if n is divisible by $\alpha(\mathrm{m})$ ． ［Since m is a factor of $\mathrm{F}_{\alpha(\mathrm{m})}$ ；if n is divisible by $\alpha(\mathrm{m}), \mathrm{F}_{\mathrm{n}}$ is divisible by $m$ ，by Lemma 5．Let $n=k \alpha(m)+r, 0 \leq r<\alpha(m)$ ，and let $m$ divide $\mathrm{F}_{\mathrm{n}}$ ．Then，by（7）， $\mathrm{F}_{\alpha(\mathrm{m})-1}^{\mathrm{k}} \mathrm{F}_{\mathrm{r}} \equiv \mathrm{F}_{\mathrm{n}} \equiv 0(\bmod \mathrm{~m})$ ．Thus，since by Lemma 1， $\left(\mathrm{F}_{\alpha(\mathrm{m})}, \mathrm{F}_{\alpha(\mathrm{m})-1}\right)=1 ; \mathrm{F}_{\mathrm{r}} \equiv 0(\bmod \mathrm{~m})$ 。Since $\mathrm{r}<\alpha(\mathrm{m})$ ，which is minimal， $\mathrm{F}_{\mathbf{r}}=0$ ；whence $\mathrm{r}=0$ and n is divisible by $\alpha(\mathrm{m})$ ．］

Lemma 9．For all integers m and $\mathrm{r} \geq \mathrm{s}>0, \alpha(\mathrm{~m}, \mathrm{~s})$ divides $\alpha(\mathrm{m}, \mathrm{r})$ ． $\left[\mathrm{F}_{\alpha(\mathrm{m}, \mathrm{r})}\right.$ is divisible by $\mathrm{m}^{\mathrm{r}}$ and so by $\mathrm{m}^{\mathrm{S}}$ ．The result follows from Lemma 8．］

Lemma 10．$\mu(\mathrm{m})$ is divisible by $\alpha(\mathrm{m})$ ．That is，$\beta(\mathrm{m})$ is an integer． ［Since $\mathrm{F}_{\mu(\mathrm{m})}^{(\mathrm{m})}=\mathrm{F}_{0}^{(\mathrm{m})}=0, \mathrm{~F}_{\mu(\mathrm{m})}$ is divisible by m 。 The lemma follows from Lemma 8．］

Lemma 11．If $p$ is an odd prime，then $p$ divides only one of $F_{p-1}$ ， $F_{p}$ ，and $F_{p+1}$ ；namely，$F_{m}$ ，where $m=p-(5 / p)$ ． $[(p, 2)=1$ 。 Using（5），（10），and（11），we obtain that

$$
\begin{equation*}
F_{p} \equiv 2^{p-1} F_{p}=\sum_{S=0}^{\frac{1}{2}(p-1)}\binom{p}{2 s+1} 5^{s} \equiv 5^{\frac{1}{2}(p-1)}(\bmod p) \tag{24}
\end{equation*}
$$

Thus $p$ divides $F_{p}$ if and only if $(5 / p)=0$ ，by（12）；that is，when $p=5$ ． By（5），（9），（10），and（11），

$$
\begin{equation*}
2 \mathrm{~F}_{\mathrm{p}+1} \equiv 2^{\mathrm{p}_{\mathrm{F}}}{ }_{\mathrm{p}+1}=\sum_{\mathrm{s}=0}^{\frac{1}{2}(\mathrm{p}-1)}\left\{\binom{\mathrm{p}}{2 \mathrm{~s}+1}+\binom{\mathrm{p}}{2 \mathrm{~s}}\right\}_{5^{s} \equiv 1+5^{\frac{1}{2}(\mathrm{p}-1)}(\bmod \mathrm{p})} \tag{25}
\end{equation*}
$$

and，by（1），（24），and（25），

$$
\begin{equation*}
2 \mathrm{~F}_{\mathrm{p}-1} \equiv 1-5^{-\frac{1}{2}(\mathrm{p}-1)}(\bmod \mathrm{p}) \tag{26}
\end{equation*}
$$

The lemma now follows．We may note that all but the dependence on（5／p） follows directly from（6），which yields that，if $p \neq 5$ ，by（11）and（24），

$$
F_{p-1} F_{p+1}=F_{p}^{2}-1 \equiv 0(\bmod p)
$$

and from（1）．］
Lemma 12。 $\alpha(\mathrm{p})$ divides $\mathrm{p}-(5 / \mathrm{p})$ ，if p is an odd prime；and if $\alpha(\mathrm{p})$ is itself prime and $\mathrm{p} \neq 5, \alpha(\mathrm{p})<\mathrm{p}$ 。
［ The first part follows from Lemmas 8 and 11．Thus $\alpha(\mathrm{p})<\mathrm{p}+1$ ．By Lem－ ma 11，if $p \neq 5$ and $\alpha(p)$ is prime，since $p \pm 1$ is not prime，$\alpha(p) \leq p-2$ ．］ Lemma 13。 If

$$
\begin{equation*}
\mathrm{m}=\mathrm{p}_{1}{ }_{1} \mathrm{p}_{2} \lambda_{2} \cdots \mathrm{p}_{\mathrm{k}}^{\mathrm{k}^{2}} \tag{27}
\end{equation*}
$$

where the $p_{i}$ are distinct primes and the $\lambda_{i}$ are positive integers，then

$$
\begin{equation*}
\alpha(\mathrm{m}, \mathrm{n})=\left[\alpha\left(\mathrm{p}_{1}, \mathrm{n} \lambda_{1}\right), \alpha\left(\mathrm{p}_{2}, \mathrm{n} \lambda_{2}\right), \cdots, \alpha\left(\mathrm{p}_{\mathrm{k}}, \mathrm{n} \lambda_{\mathrm{k}}\right)\right] \tag{28}
\end{equation*}
$$

and

$$
\begin{equation*}
\mu(\mathrm{m}, \mathrm{n})=\left[\mu\left(\mathrm{p}_{1}, \mathrm{n} \lambda_{\mathrm{i}}\right), \mu\left(\mathrm{p}_{2}, \mathrm{n} \lambda_{2}\right), \cdots, \mu\left(\mathrm{p}_{\mathrm{k}}, \mathrm{n} \lambda_{\mathrm{k}}\right)\right] \tag{29}
\end{equation*}
$$

［By Lemma 8，$F_{t}$ is divisible by $p_{i}^{n} \lambda_{i}$ if and only if $t$ is divisible by $\alpha\left(p_{i}\right.$ ， $\mathrm{n}_{\lambda_{\mathrm{i}}}$ ）．Thus $\mathrm{F}_{\mathrm{t}}$ is divisible by $\mathrm{m}^{\mathrm{n}}$ if and only if t is a multiple of all the $\alpha\left(p_{i}, n \lambda_{i}\right)$ 。 Since $\alpha(m, n)$ is minimal，（28）follows．By Lemma 6，$F_{s+t} \equiv$ $F_{s}\left(\bmod p_{i}^{n} \lambda_{i}\right)$ for every $s$ if and only if $t$ is a multiple of $\mu\left(p_{i}, n \lambda_{i}\right)$ ．Thus， by the Chinese remainder theorem， $\mathrm{F}_{\mathrm{S}+\mathrm{t}} \equiv \mathrm{F}_{\mathrm{S}}\left(\bmod \mathrm{m}^{\mathrm{n}}\right)$ for every s if and only if $t$ is a common multiple of the $\mu\left(p_{i}, n \lambda_{i}\right)$ ．Since $\mu(m, n)$ is the mini－ mal such $t$ ，（29）follows．］

Lemma 14．For any integers $m$ and $n$ ，

$$
\alpha([\mathrm{m}, \mathrm{n}])=[\alpha(\mathrm{m}), \alpha(\mathrm{n})]
$$

and

$$
\mu([\mathrm{m}, \mathrm{n}])=[\mu(\mathrm{m}), \mu(\mathrm{n})]
$$

［This follows from Lemma 13，by expanding $m$ and $n$ in prime factors．］
Definition 7．The greatest integer $n$ such that $N$ is divisible by $m^{n}$ will be written

$$
\begin{equation*}
\mathrm{n}=\operatorname{pot}_{\mathrm{m}} \mathrm{~N} \tag{31}
\end{equation*}
$$

and called the＂potency＂of N to base m ，following H 。 Gupta．It is then clear that，in particular，

$$
\begin{equation*}
v(\mathrm{~m}, \mathrm{n})=\operatorname{pot}_{\mathrm{m}} \mathrm{~F}_{\alpha(\mathrm{m}, \mathrm{n})} \tag{32}
\end{equation*}
$$

Lemma 15． $\operatorname{pot}_{\mathrm{m}} \mathrm{F}_{\mathrm{N}}=\mathrm{n}$ if and only if N is divisible by $\alpha(\mathrm{m}, \mathrm{n})$ but not by $\alpha(m, n+1)$ 。
［This is an immediate consequence of Lemma 8．］
Lemma 16．If $k$ and $n$ are positive integers，then（ $F_{k n} / F_{n}, F_{n}$ ）is a factor of $k$ 。
$\left[\operatorname{By}(8), \mathrm{F}_{\mathrm{kn}} / \mathrm{F}_{\mathrm{n}} \equiv \mathrm{kF}_{\mathrm{n}-1}^{\mathrm{k}-1}\left(\bmod \mathrm{~F}_{\mathrm{n}}\right)\right.$ 。Thus，if $\left(\mathrm{F}_{\mathrm{kn}} / \mathrm{F}_{\mathrm{n}}, \mathrm{F}_{\mathrm{n}}\right)=\mathrm{g}, \mathrm{g}$ divides $\mathrm{k} \mathrm{F}_{\mathrm{n}-1}^{\mathrm{k}-1}$ ．By Lemma 1 ，$\left(\mathrm{F}_{\mathrm{n}-1}, \mathrm{~F}_{\mathrm{n}}\right)=1$ ；so g divides $\mathrm{k}_{\text {。 }}$ ］

Lemma 17．If k and n are both integers greater than one，then $\mathrm{F}_{\mathrm{kn}} / \mathrm{F}_{\mathrm{n}}$ is a strictly increasing function of n and of $\mathrm{k}_{0}$
［By（8），$F_{k n} / F_{n}=\Sigma_{h=1}^{k}\binom{k}{h} F_{n}^{h-1} F_{n-1}^{k-h} F_{h^{*}}$ Every term in the sum is positive， and increases with $\mathrm{F}_{\mathrm{n}}, \mathrm{F}_{\mathrm{n}-1}$ ，and $\mathrm{k}_{\text {。 }}$ The result follows from Lemma 2。］

Of these results，those in Lemmas 1，2，4－7，11，and 16 have been known for a long time．Lemmas $8-10$ and $12-15$ appear，or are implicit，in the papers of Robinson［5］，Vinson［6］，and Wall［7］［ $\mathrm{My} \alpha(\mathrm{m}), \beta(\mathrm{m}), \quad \mu(\mathrm{m})$ are written $\alpha(\mathrm{m}), \beta(\mathrm{m}), \delta(\mathrm{m})$ by Robinson，and $\mathrm{f}(\mathrm{m}), \mathrm{t}(\mathrm{m}), \mathrm{s}(\mathrm{m})$ by Vinson， respectively；and Wall writes $\mathrm{d}(\mathrm{m}), \mathrm{k}(\mathrm{m})$ for my $\alpha(\mathrm{m}), \mu(\mathrm{m})$ 。］

## 3．THE DIVISIBILITY SEQUENCE

Theorem 1。 If p is an odd prime and $\mathrm{n} \geq \nu(\mathrm{p})$ ，then

$$
\begin{equation*}
\alpha(\mathrm{p}, \mathrm{n})=\mathrm{p}^{\mathrm{n}-v(\mathrm{p})} \alpha(\mathrm{p}) \tag{33}
\end{equation*}
$$

$$
\begin{equation*}
v(\mathrm{p}, \mathrm{n})=\mathrm{n} \tag{34}
\end{equation*}
$$

If $\mathrm{p} \neq 5, \quad(\mathrm{p}, \alpha(\mathrm{p}))=1$ ；while

$$
\begin{equation*}
\alpha(5, n)=5^{n} \tag{35}
\end{equation*}
$$

Further，

$$
\begin{equation*}
\alpha(2)=3, \alpha(4)=6=\alpha(8) \tag{36}
\end{equation*}
$$

and if $n \geq 3$ ，

$$
\begin{equation*}
\alpha(2, \mathrm{n})=2^{\mathrm{n}-2} \alpha(2)=2^{\mathrm{n}-2} \cdot 3 \tag{37}
\end{equation*}
$$

Proof．By Lemma 9，$\alpha(\mathrm{p}, \mathrm{n})=\mathrm{k} \alpha(\mathrm{p}, \mathrm{n}-1)$ ，for some integer k 。Write

$$
\mathrm{F}_{\alpha(\mathrm{p}, \mathrm{n})}=\mathrm{p}^{\mathrm{n}} \mathrm{~A}, \mathrm{~F}_{\alpha(\mathrm{p}, \mathrm{n}-1)}=\mathrm{p}^{\mathrm{n}-1} \mathrm{~B}, \mathrm{~F}_{\alpha(\mathrm{p}, \mathrm{n}-1)-1}=\mathrm{C}_{0}
$$

Then，by（8），

$$
\begin{equation*}
\mathrm{pA}=\sum_{h=1}^{k}\binom{k}{h} p^{(n-1)(h-1)} B^{h} C^{k-h} F_{h} \tag{38}
\end{equation*}
$$

Thus，if $n>\nu(p) \geq 1$ ，since $(p, C)=1$ ，$k B$ must be divisible by $p$ ．Hence， if $v(p, n-1)=n-1,(p, B)=1$ ，whence $p$ divides $k_{0}$ Since $\alpha(p, n)$ and so $k$ ，is minimal，$k=p$ ．Now，by（10），since $k>2$ ，（38）yields that $A \equiv$ $\mathrm{BC}^{\mathrm{p}-1}(\bmod \mathrm{p})$ ．Since the factors on the right are prime to p ，so is $A$ ， whence $v(\mathrm{p}, \mathrm{n})=\mathrm{n}$ 。 By（18），$v(\mathrm{p}, \nu(\mathrm{p}))=\nu(\mathrm{p})$ ，so that，by induction，if $\mathrm{n} \geq$ $\nu(\mathrm{p}), \quad(34)$ holds and $\alpha(\mathrm{p}, \mathrm{n})=\mathrm{p}^{\mathrm{n}-\nu(\mathrm{p})} \alpha(\mathrm{p}, \nu(\mathrm{p}))$ 。 By（17），$\alpha(\mathrm{p}, \nu(\mathrm{p}))=\alpha(\mathrm{p})$, yielding（33）。

By Lemma 12，$\alpha(p)$ divides $p-(5 / p)$ ．Thus，if $p \neq 5,(p, \alpha(p))=1$ 。 If $p=5$ ，then，by $(2), \alpha(5)=5, v(5)=1$ ，and，by（33），we get（35）．

Finally，if $p=2,(38)$ still holds，and we see，as before，that $k=p$ $=2$ if $v(2, \mathrm{n}-1)=\mathrm{n}-1$ ．Thus $2 \mathrm{~A}=2^{\mathrm{n}-1} \mathrm{~B}^{2}+2 \mathrm{BC}$ ，whence $(2, \mathrm{~A})=1$ and $\nu(2, n)=n$ ，as before，if $n \geq 3$ ．By（2），we have（36），whence we obtain （37）like（33）．

Theorem 2．If pot $\mathrm{F}_{\mathrm{m}}=\mathrm{n} \geq 1$ ，where p is prime and $\mathrm{p}^{\mathrm{n}} \neq 2$ ，and if $r \geq 0$ and $(p, t)=1$ ；then pot ${ }_{p}{ }^{F}{ }_{p} r_{t m}=n+r$ ．If $p^{n}=2, \quad t m$ is an odd multiple of 3 and $F_{t m}$ is an odd multiple of 2，while，if $r \geq 1, \operatorname{pot}_{2} F{ }_{2} r_{t m}=$ $r+2$ 。

Proof．We repeatedly use Lemma 15 and Theorem 1．If $n \geq 1$ and $p^{n}$ $\neq 2$ ，either p is odd and $\mathrm{n} \geq v(\mathrm{p})$ ，or $\mathrm{p}=2$ and $\mathrm{n} \geq 3$ ；whence，by（33） or（37），

$$
\begin{equation*}
\alpha(\mathrm{p}, \mathrm{n}+\mathrm{r})=\mathrm{p}^{\mathrm{r}} \alpha(\mathrm{p}, \mathrm{n}) \tag{39}
\end{equation*}
$$

Thus，$m=k \alpha(p, n)$ for some $k$ prime to $p$ ．Hence $p^{r_{t m}}=\operatorname{tk} \alpha(p, n+r)$ ，so that pot ${ }_{p}{ }_{p^{p} r_{t m}}=n+r$ ．By（36），if $p^{n}=2, m$ and $t m$ are divisible by 3 but not by 6 ，so that $\operatorname{pot}_{2} \mathrm{~F}_{\mathrm{tm}}=1$ ，and similarly by（37）， $\operatorname{pot}_{2} \mathrm{~F}_{2} \mathrm{r}_{\mathrm{tm}}=\mathrm{r}+2$ ， if $r \geq 1$ 。

Theorems 1 and 2 have a fairly long history．Lucas［4］（see pages 209－ 210）proved the simplest formula（39）with $r=1$ ，but failed to notice the anomaly
when $\mathrm{p}^{\mathrm{n}}=2$ 。 Carmichael [1] (see pages $40-42$ ) proved Theorem 2 in full,* using the theory of cyclotomic polynomials。Both Lucas' and Carmichael's results apply to a more general sequence** than that defined by (1) and (2). Robinson [5] proves Theorem 1, for odd primes only, by a matrix method.

Theorem 3. If pot ${ }_{p} \mathrm{~F}_{\mathrm{m}}=\mathrm{n} \geq 1$, where p is prime and $\mathrm{p}^{\mathrm{n}} \neq 2$, and if $r \geq 0$; then there is a strictly increasing sequence of pairwise prime integers $\ell_{S}=\ell_{S}(m, p)(S=0,1,2,9 \circ \circ)$, all prime to $p$, such that

$$
\begin{equation*}
\mathrm{F}_{\mathrm{p}^{\mathrm{r}} \mathrm{~m}}=\mathrm{p}^{\mathrm{n}+\mathrm{r}}{\ell_{0} \ell_{1}}^{\cdots} \ell_{\mathrm{r}} \tag{40}
\end{equation*}
$$

Proof. When $r=0$, we define $F_{m}=p^{n} \ell_{0}$, where $\left(p, \ell_{0}\right)=1$. By Theorem 2, if $r \geq 1$, there are integers $A, B$, and $C$, such that

$$
\mathrm{F}_{\mathrm{p}^{r} m}=\mathrm{p}^{\mathrm{n}+\mathrm{r}} A, \mathrm{~F}_{\mathrm{p}^{\mathrm{r}-1} \mathrm{~m}}=\mathrm{p}^{\mathrm{n+r-1}} B, \mathrm{~F}_{\mathrm{p}^{r-1} m-1}=\mathrm{C}
$$

and $(p, A)=(p, B)=1$, while, by Lemma $1,(p B, C)=1$. Thus, by (8),

$$
\begin{equation*}
A=B \sum_{h=1}^{p}\binom{p}{h} p^{(n+r-1)(h-1)-1} B^{h-1} C^{p-h_{h}} F_{h} \tag{41}
\end{equation*}
$$

where, as in the proof of Theorem 1, the sum on the right is an integer, since $\mathrm{n} \geq 1$. Thus $A$ is divisible by $B$. If we write $A=\ell_{r} B$, it is clear that $A=\ell_{0} l_{1} \cdots \ell_{r}$, yielding (40). Further (41) gives us that

$$
\begin{equation*}
\ell_{r}=p B \sum_{h=2}^{p}\binom{p}{h} p^{(n+r-1)(h-1)-2} B^{h-2} C^{p-h} F_{h}+C^{p-1} \tag{42}
\end{equation*}
$$

[^0]where the sum is again an integer, since either $p \geq 3$ and $n \geq 1$, or $p=2$ and $n \geq 3$ 。 Thus $\ell_{r} \equiv C^{p-1}(\bmod p B)$; so that, since $C$ is prime to $p$, $\ell_{0}, \ell_{1}, \cdots,{ }_{r-1}$, so is $\ell_{r}$. Again, since $\ell_{r}$ exceeds a positive integer multiple of pB , we have that
\[

$$
\begin{equation*}
\ell_{r}>p l_{0} l_{1} \cdots l_{r-1}>l_{r-1} . \tag{43}
\end{equation*}
$$

\]

Corollary 1. If pot ${ }_{p} \mathrm{~F}_{\mathrm{m}}=\mathrm{n} \geq 1$ and $\mathrm{p}^{\mathrm{n}} \neq 2$, and if $\mathrm{r}>\mathrm{s} \geq 0$, then

$$
\begin{equation*}
\ell_{r-s}\left(p^{s} m, p\right)=\ell_{r}(m, p) \tag{44}
\end{equation*}
$$

and

$$
\begin{equation*}
\ell_{0}\left(p^{s} m, p\right)=\ell_{0}(m, p) \ell_{1}(m, p) \cdots \ell_{S}(m, p) \tag{45}
\end{equation*}
$$

Corollary 2. If pot $_{2} \mathrm{Fm}=1$ and $\mathrm{r} \geq 1$, then

$$
\begin{equation*}
\mathrm{F}_{2^{\mathrm{r}} \mathrm{~m}}=2^{\mathrm{r}+2} \ell_{0}(2 \mathrm{~m}, 2) \ell_{1}(2 \mathrm{~m}, 2) \cdots^{\circ} \ell_{\mathrm{r}-1}(2 \mathrm{~m}, 2) \quad . \tag{46}
\end{equation*}
$$

Theorem 3, with its corollaries, contains a definition of $\ell_{S}(m, p)$ whenever $\operatorname{pot}_{p} F_{m}=n \geq 1$ and $p^{n} \neq 2$. By analogy with (40), (44), (45) and (46), we shall adopt the following definition for the remaining case。

Definition 8. If $\mathrm{m}=3 \mathrm{t}$ where t is odd (so that, by Theorem 2, $\operatorname{pot}_{2} \mathrm{~F}_{\mathrm{m}}$ $=1$ ), the sequence $\ell_{S}(m, 2)$ is defined by

$$
\begin{equation*}
\ell_{1}(\mathrm{~m}, 2)=2 \ell_{0}(2 \mathrm{~m}, 2) / \ell_{0}(\mathrm{~m}, 2), \tag{48}
\end{equation*}
$$

and

$$
\begin{equation*}
\ell_{\mathrm{S}}(\mathrm{~m}, 2)=\ell_{\mathrm{S}-1}(2 \mathrm{~m}, 2) \text { if } \mathrm{s} \geq 2 \tag{49}
\end{equation*}
$$

Corollary 3. Adopting Definition 8, we obtain equation (40) for every prime $p$, and every positive integer $m$ such that pot $_{p} F_{m}=n \geq 1$. In every case, the numbers $\ell_{s}=\ell_{s}(m, p)(s=0,1,2, \cdots)$ are integers, all pairwise prime, and all but $\ell_{1}(m, p)$ are always prime to $p$. If $m$ is an odd multiple of $3, \ell_{1}(\mathrm{~m}, 2)$ is an odd multiple of 2 ; in every other case, $\ell_{1}(\mathrm{~m}, \mathrm{p})$ is prime to p 。

Proof. If $\mathrm{p}^{\mathrm{n}} \neq 2$, the corollary coincides with Theorem 3. If $\mathrm{p}^{\mathrm{n}}=2$ (that is, $m$ is an odd multiple of 3 , by (36)) and $r \geq 1$, Corollary 2 and Definition 8 (equations (46), (48), and (49)) show that equation (40) holds, with $\frac{1}{2} \ell_{0}(\mathrm{~m}, 2) \ell_{1}(\mathrm{~m}, 2), \ell_{2}(\mathrm{~m}, 2), \ell_{3}(\mathrm{~m}, 2), \cdots \quad$ all pairwise prime odd integers, by Theorem 3. Finally, when $p^{n}=2$ and $r=0$, we get (40) from the definition (47), and, by Theorem 2, $\ell_{0}(\mathrm{~m}, 2)$ is an odd integer.

Further, by (8), $F_{2 m}=F_{m}\left(F_{m}+2 F_{m-1}\right)$, which yields through (40) that $\ell_{1}(m, 2)=\ell_{0}(m, 2)+F_{m-1}$. Since $\left(\ell_{0}, F_{m-1}\right)=\left(\ell_{1}, F_{m-1}\right)=1$ (by Lemma 4), and both $\ell_{0}$ and $F_{m-1}$ are odd, we see that $\ell_{1}(m, 2)$ is even and prime to $\ell_{0}(m, 2)$. Finally, since $\frac{1}{2} \ell_{0} \ell_{1}$ is odd, $\ell_{1}$ must be an odd multiple of 2.

Theorem 4o Let $P=\left\{p_{1}, p_{2}, \cdots, p_{k}\right\}$ be a set of $k$ distinct primes. Then $P$ contains all the prime factors of $F_{p_{1}}, F_{p_{2}}, \cdots, F_{p k}$ only if

$$
\left\{\begin{align*}
& \mathrm{k}=1 \text { and } P=\{2\} \text { or }\{5\}  \tag{50}\\
& \mathrm{k}=2 \text { and } \mathrm{P}=\{2,3\} \text { or }\{2,5\} \\
& \text { or } \\
& \mathrm{k}=3 \text { and } P=\{2,3,5\}
\end{align*}\right.
$$

Proof. Let $k=1$. Then $F_{p_{1}}$ can have no prime factor other than $p_{1}$. By (2), Lemma 2, and Lemma 11, the only possible values of $p_{1}$ are 2 and 5 。

Let $k \geq 2$, and first suppose that $2 \notin P$. By Lemma 4, if $i \neq j_{\text {. }}$, $\left(\mathrm{F}_{\mathrm{p}_{\mathrm{i}}}, \mathrm{F}_{\mathrm{p}_{\mathrm{j}}}\right)=1$, so that no prime factor is common to two of the $\mathrm{F}_{\mathrm{p}_{\mathrm{i}}}$; and by Lemma 2, since every $p_{i} \geq 3$, every $F_{p_{i}}$ has at least one prime factor. Thus every $F_{p_{i}}$ has exactly one prime factor. Let us now renumber the $p_{i}$, if necessary, so that $p_{1}$ is the least prime in $P$ not equal to 5 , and

$$
\begin{equation*}
\mathrm{F}_{\mathrm{p}_{1}}=\mathrm{p}_{2}^{\mathrm{r}_{2}}, \mathrm{~F}_{\mathrm{p}_{2}}=\mathrm{p}_{3}^{r_{3}}, \cdots, \mathrm{~F}_{\mathrm{p}_{\mathrm{i}-1}}=\mathrm{p}_{\mathrm{i}}^{\mathrm{r}_{\mathrm{i}}}, \cdots \tag{51}
\end{equation*}
$$

where each $r_{i} \geq 1$. This can always be done, and, since $p_{1} \neq 5$, inductively $\mathrm{p}_{2}, \mathrm{p}_{3}, \cdots \neq 5$, and no $\mathrm{p}_{\mathrm{i}-1}=\mathrm{p}_{\mathrm{i}}$. Finally, by Lemma 8, each $\mathrm{p}_{\mathrm{i}-1}=\alpha\left(\mathrm{p}_{\mathrm{i}}\right)$ and so, by Lemma 12, $\alpha\left(p_{i}\right)=p_{i-1}<p_{i}$. Thus the sequence defined by (51) cannot terminate, and this contradicts the finiteness of $P$. Therefore $2 \in P$ and we may write $p_{1}=2$. If the $F_{p_{i}}(i=2,3, \cdots, k)$ are all odd, the $p_{i}(i=$ $2,3, \cdots, k)$ from a set of $k-1$ distinct odd primes containing all the prime factors of the corresponding set of $\mathrm{F}_{\mathrm{p}_{\mathrm{i}}}$. We have just shown that this can only happen if $k-1=1$ and $p_{2}=5$. Suppose now that one of the $F_{p_{i}}$ is even. Then, by (2), we can write $p_{2}=3$, since $F_{3}=2$ 。 If $\mathrm{k}=2$, this completes the enumeration of possible cases. If $k \geq 3$, then $p_{3}, p_{4}, \cdots, p_{k}$ form a set of $\mathrm{k}-2$ distinct oddprimes containing all the primefactors of the corresponding set of $\mathrm{F}_{\mathrm{p}_{\mathrm{i}}}$, because $\alpha(3)=4$, which is not prime. Again, we know that this can only happen if $k-2=1$ and $p_{3}=5$. This completes the proof.

Definition 9. If $\operatorname{pot}_{\mathrm{p}} \mathrm{F}_{\mathrm{N}}=\mathrm{n}$, and if either $\mathrm{n} \geq 1$ and $\mathrm{p}=5$, or $\mathrm{n}>$ $\nu(\mathrm{p})$, we shall call p a multiple prime factor (mpf) of $\mathrm{F}_{\mathrm{N}^{\circ}}$ If, on the contrary, $\mathrm{p} \neq 5$ and $\mathrm{n}=\nu(\mathrm{p})$, then p is a simple prime factor ( spf ) of $\mathrm{F}_{\mathrm{N}}$.

Lemma 18。 p is a multiple prime factor of $\mathrm{F}_{\mathrm{N}}$ if and only if it is a prime factor of both $F_{N}$ and $N$. A prime factor of $F_{N}$ which is not multiple is a simple prime factor.
[This follows from Definition 9, Lemma 8, and Theorem 1.]
Lemma 19. If k and n are positive integers and p is a multiple prime factor of $F_{n}$, it is also a multiple prime factor of $F_{k n}$. Conversely, if $p$ is a simple prime factor of $F_{k n}$, it is also a simple prime factor of $F_{n}$. [This follows from Lemmas 5 and 18.]

Theorem 5. $\mathrm{F}_{\mathrm{N}}$ has at least one simple prime factor, unless $\mathrm{N}=1,2$, 5,6 , or 12 .

Proof. $F_{1}=F_{2}=1$, so that these $F_{N}$ have no prime factors at all, and so no spf, as stated. Let $N \geq 3$, and let $F_{N}=m$ satisfy (27). By Lemma 2, the set $P$ of prime factors of $F_{N}$ is not empty. If $F_{N}$ has only mpfs, by Lemma 16, each $p_{i}$ divides $N$; whence by Lemma 5, each $F_{p_{i}}$ divides $m$. It follows that $P$ contains all the prime factors of every $F_{p_{i}}$. This is the situation dealt with in Theorem 4, and it can only occur in the five cases listed in (50).

By (2), (50), Lemma 8, and Theorem 1, if $F_{N}$ has only mpfs, we see that $F_{N}=2^{r} \cdot 3^{s} \cdot 5^{t}$. Further, $r \leq 4 ; s \leq 2 ; t \leq 1 ; r t=0 ; s t=0 ;$ if
$r=0$ then $s=0$ and $t=1$; if $s=t=0$ then $r=3$; if $r s>0$ then $r=$ 4 and $s=2$ 。Thus $F_{N}=5,8$, or 144 ; whence $N=5,6$, or 12 ; and all these cases are valid and stated in the theorem.

## 4. CARMICHAEL'S THEOREM

By using the theory of cyclotomic polynomials, Carmichael proved, for the general sequence* $D_{n}$, a theorem which, in our terminology, reads as follows [Compare [1], Theorem XXIII, pages 61-62.]

Carmichael's Theorem。 If $\mathrm{N} \neq 1,2,6$, or 12 , then there is a prime p , such that $\mathrm{N}=\alpha(\mathrm{p})$.

We shall proceed to derive this theorem, for the Fibonacci sequence, by the elementary considerations we have used so far. Let

$$
\begin{equation*}
N=q_{1}^{n_{1}} q_{2}^{n_{2}} \ldots q_{k}^{n_{k}} \tag{52}
\end{equation*}
$$

where the $q_{i}$ are distinct primes and the $n_{i} \geq 1$. We shall write $N_{(1)}$ for any of the $k$ integers $N_{i}=N / q_{i}$, and more generally $N_{(h)}$ for any of the $\binom{k}{h}$ integers $N / q_{i_{1}} q_{i_{2}} \cdots q_{i_{h}}$, with $\left\{i_{1}, i_{2}, \cdots, i_{h}\right\}$ a subset (without repetition) of $\{1,2, \cdots, k\}$. We shall also write $R_{h}$ for the product of the $\binom{k}{h}$ integers ${ }^{-}{ }_{N(h)}$.

Lemma 20. If N satisfies (52), then

$$
\begin{equation*}
\left[F_{N_{1}}, F_{N_{2}}, \cdots, F_{N_{k}}\right]=\frac{R_{1} R_{3} R_{5} \cdots}{R_{2} R_{4} R_{6} \cdots}=\prod_{h=1}^{h} R_{h}^{(-1)^{h-1}} \tag{53}
\end{equation*}
$$

[By repeated application of Lemma 4, we see that

$$
\begin{align*}
& \left.\left(F_{N_{i_{1}}}, F_{N_{i_{2}}} \cdots, F_{N_{i_{h}}}\right)=F_{\left(N / q_{i_{1}}\right.} N / q_{i_{2}}, \cdots, N / q_{i_{h}}\right)= \\
&  \tag{54}\\
& F_{N / q_{i_{1}} q_{i_{2}}} \cdots q_{i_{h}}=F_{N}(h)
\end{align*}
$$

${ }^{*}$ See footnote on page 227 above.
so that $R_{h}$ is the product of the greatest common factors of all sets of $h$ numbers $F_{N_{(1)}}$ 。 Let a prime factor $p$ divide exactly $s_{1}$ of the $F_{N_{(1)}}$; and let $p^{2}, p^{3}, \cdots, p^{m}$ divide $s_{2}, s_{3}, \cdots, s_{m}$ of the $F_{N_{(1)}}$, respectively; but let no $F_{N_{(1)}}$ be divisible by $p^{m+1}$. Then $k \geq s_{1} \geq s_{2} \geq \ldots \geq s_{m} \geq 1$ and $\operatorname{pot}_{p}\left[F_{N_{1}}, F_{N_{2}}, \cdots, F_{N_{k}}\right]=m$. Of the $\binom{k}{h}$ factors in $R_{h}$, (54) shows that $\binom{s_{1}}{h},\binom{s_{2}}{h}, \cdots,\binom{s_{m}}{h}$ are respectively divisible by $p, p^{2}, \cdots, p^{m}$ 。 (Note that $\binom{s}{h}=0$ if $s<h$, and that the set of factors divisible by $p$ includes those divisible by $\mathrm{p}^{2}$, which include those divisible by $\mathrm{p}^{3}$, and so on). Thus $\operatorname{pot}_{p} R_{h}=\binom{s_{1}}{h}+\binom{s_{2}}{h}+\cdots+\binom{s_{m}}{h}$, whence $\operatorname{pot}_{p}\left(\frac{R_{1} R_{3} R_{5} \cdots}{R_{2} R_{4} R_{6} \cdots o}\right)=\sum_{t=1}^{m} \sum_{h=1}^{k}(-1)^{h-1}\left(\begin{array}{c}s \\ t \\ h\end{array}\right)=\sum_{t=1}^{m}\left\{1-(1-1)^{s^{t}}\right\}=m$,
which implies (53).]
It follows from Lemmas 5 and 20 that

$$
\begin{equation*}
Q_{N}=\frac{F_{N} R_{2} R_{4} \cdots}{R_{1} R_{3} R_{5} \cdots}=\frac{F_{N}}{\left[F_{\left.N_{1}, F_{N_{2}}, \cdots, F_{N_{k}}\right]}\right. \text {, }} \tag{55}
\end{equation*}
$$

is a positive integer. [Carmichael [1] writes $\mathrm{D}_{\mathrm{N}}$ for my $\mathrm{F}_{\mathrm{N}}$, and $\mathrm{F}_{\mathrm{N}}(\alpha, \beta)$ $=\beta^{\phi(N)} \mathrm{Q}_{\mathrm{N}}(\alpha / \beta)$ for my $\mathrm{Q}_{\mathrm{N}}$, where

$$
\begin{equation*}
\phi(N)=q_{1}^{n_{1}-1}\left(q_{1}-1\right) q_{2}^{n_{2}-1}\left(q_{2}-1\right) \cdots q_{k}^{n_{k} k^{-1}}\left(q_{k}-1\right) \tag{56}
\end{equation*}
$$

in the Euler $\phi$-function.]

By (55) and Theorem 2, if a prime $p$ divides $Q_{N}$, it is either a factor of $\mathrm{F}_{\mathrm{N}}$ which is prime to every $\mathrm{F}_{\mathrm{N}_{(1)}}$, or it also divides some $\mathrm{F}_{\mathrm{N}_{(1)}}$. In the former case, by Lemma 8, since $\alpha(\mathrm{p})$ divides N , but no $\mathrm{N}_{(1)}$, necessarily $\mathrm{N}=\alpha(\mathrm{p})$, and if $\mathrm{N} \neq 5, \mathrm{p} \neq 5$ and p is a spf of $\mathrm{F}_{\mathrm{N}^{\circ}}$. In the latter case, by Theorem 2, p is a mpf of $\mathrm{F}_{\mathrm{N}}$, and $\operatorname{pot}_{\mathrm{p}} \mathrm{Q}_{\mathrm{N}}=1$, except if $\mathrm{N}=6$ (when $Q_{N}=Q_{6}=F_{6} F_{1} / F_{2} F_{3}=4_{\circ}$ )

Lemma 21. If N satisfies (52) and

$$
\begin{equation*}
Q_{N}>q_{1} q_{2} \cdots q_{k}, \tag{57}
\end{equation*}
$$

then there is a prime p such that $\mathrm{N}=\alpha(\mathrm{p})$.
[As explained above, if $N=6, Q_{N}=4<2 \cdot 3$, so this case does not axise. Thus $\operatorname{pot}_{p} Q_{N}=0$ or 1 and $Q_{N} / q_{1} q_{2} \cdots q_{k}$ cannot be divisible by any $q_{i}$. Thus if this quotient exceeds one, $\mathrm{Q}_{\mathrm{N}}$ must be divisible by some prime other than the $q_{i}$, and such a prime p has $\left.\mathrm{N}=\alpha(\mathrm{p})_{0}\right]$

Lemma 22. If N satisfies (52) and $\mathrm{k} \geq 4$, then (57) holds.
[Since $R_{h}$ has $\binom{k}{h}$ Fibonacci-number factors, and since
$\sum_{h=0}^{k}\binom{k}{h}=(1+1)^{k}=2^{k} \quad$ and $\quad \sum_{h=0}^{k}(-1)^{h}\binom{k}{h}=(1-1)^{k}=0 \quad$,
we see that the numerator and denominator of $Q_{N}$, by (55), each has $2^{k-1}$ Fibonacci-number factors. Also, by (4), if $\mathrm{a}=(1 / 2)(\sqrt{5}+1)$ and $\mathrm{b}=$ $(1 / 2)(\sqrt{5}-1)$ so that $\mathrm{a}>1>\mathrm{b}=1 / \mathrm{a} \quad$ [Carmichael writes $\alpha$ and $-\beta$ for my a and b],
(58) $a^{n}\left(1-b^{2}\right) \leq a^{n}\left(1-b^{2 n}\right) \leq \sqrt{5} F_{n} \leq a^{n}\left(1+b^{2 n}\right) \leq a^{n}\left(1+b^{2}\right)$.

Therefore, since $\left(1-b^{2}\right) /\left(1+b^{2}\right)=1 / \sqrt{5}$ and by (55) and (58), $Q_{N} \geq a^{f}(1 / \sqrt{5})^{2}{ }^{k-1}$, where, by (56),
$f=N-\Sigma N_{(1)}+\Sigma N_{(2)}-\cdots=N\left(1-\frac{1}{q_{1}}\right)\left(1-\frac{1}{q_{2}}\right) \cdots\left(1-\frac{1}{q_{k}}\right)=\phi(N) ;$
[Oct.
so that

$$
\begin{equation*}
Q_{N} \geq a^{\phi(N)}(1 / \sqrt{5})^{2} k-a^{\left(q_{1}-1\right)\left(q_{2}-1\right) \cdots\left(q_{k}-1\right)}(1 / \sqrt{5})^{2}{ }^{k-1} \tag{59}
\end{equation*}
$$

Clearly $\left(q_{1}-1\right)\left(q_{2}-1\right) \cdots\left(q_{k}-1\right)$ exceeds the value when we put $q_{1}=2$ and $q_{i}=2 i-1 \quad(i \geq 2)$, namely $q^{k-1}(k-1)!$. The function

$$
2^{k}+\sum_{i=1}^{k}\left(q_{i}-1\right)
$$

increases more slowly with each $q_{i}$ than does the product, and its value at the minimal point is $2^{k}+k^{2}-k+1$. If $k \geq 4$, this i.s seen to be less than $2^{k-1}(k-1)!$ 。Thus, by (59),

$$
\begin{equation*}
Q_{N} \geq\left\{\prod_{i=1}^{k} a^{q_{i}-1}\right\}\left(a^{2} / \sqrt{5}\right)^{8} \tag{60}
\end{equation*}
$$

The function $a^{n-1} / n$ has a minimum for integex values of $n$ when $n=2$, and it exceeds one when $n \geq 4$. Thus, by (60),
(61) $\mathrm{Q}_{\mathrm{N}} / q_{1} q_{2} \cdots q_{k} \geq(a / 2)\left(a^{2} / 3\right)\left(a^{4} / 5\right)\left(a^{6} / 7\right)\left(a^{2} / N 5\right)^{8}=a^{29} / 131250>8$, and the lemma follows.]

Lemma 23. If N satisfies (52) and $\mathrm{k}=3$, then (57) holds if at least one $q_{i} \geq 11$, or if no $q_{i}=2$, or if any $n_{i} \geq 2$ 。
[As in the proof of Lemma 21, (59) still holds. Now, if we suppose that $q_{i}<$ $q_{2}<q_{3}$, we see that $q_{1} \geq 2, q_{2} \geq 3$, and, by the first supposition of the lemma, $q_{3} \geq 11$. Thus
$\left(q_{1}-1\right)\left(q_{2}-1\right)\left(q_{3}-1\right)=\left(q_{1}-1\right)\left(q_{2}-1\right)\left(q_{3}-2\right)+\left(q_{1}-1\right)\left(q_{2}-2\right)+\left(q_{1}-1\right)$

$$
\geq 2\left(q_{3}-2\right)+\left(q_{2}-2\right)+\left(q_{1}-1\right) \geq\left(q_{1}-1\right)+\left(q_{2}-1\right)+\left(q_{3}-1\right)+7
$$

and so, by (59) and (62), as before,

$$
\begin{equation*}
\mathrm{Q}_{\mathrm{N}} / \mathrm{q}_{1} q_{2} q_{3} \geq(\mathrm{a} / 2)\left(\mathrm{a}^{2} / 3\right)\left(\mathrm{a}^{10} / 11\right)\left(\mathrm{a}^{7} / 5^{2}\right)=\mathrm{a}^{20} / 1650>9 \tag{63}
\end{equation*}
$$

and (57) follows.
Adopting the second supposition, we have $q_{1} \geq 3, q_{2} \geq 5$, and $q_{3} \geq 7$ Then (62) is replaced by
(64) $\quad\left(q_{1}-1\right)\left(q_{2}-1\right)\left(q_{3}-1\right) \geq 8\left(q_{3}-2\right)+2\left(q_{2}-2\right)+q_{1}-1 \geq\left(q_{1}-1\right)+\left(q_{2}-1\right)+$ $+\left(q_{3}-1\right)+36$, and (63) by

$$
\begin{equation*}
\mathrm{Q}_{\mathrm{N}} / \mathrm{q}_{1} q_{2} q_{3} \geq\left(\mathrm{a}^{2} / 3\right)\left(\mathrm{a}^{4} / 5\right)\left(\mathrm{a}^{6} / 7\right)\left(\mathrm{a}^{36} / 5^{2}\right)=\mathrm{a}^{48} / 2625>10^{6} \tag{65}
\end{equation*}
$$

and (57) follows again.
Finally, if any $n_{i} \geq 2, \phi(n) \geq 2\left(q_{1}-1\right)\left(q_{2}-2\right)\left(q_{3}-1\right)$. Thus, as before, $q_{1} \geq 2, q_{2} \geq 3, q_{3} \geq 5$, and $2\left(q_{1}-1\right)\left(q_{2}-1\right)\left(q_{3}-1\right) \geq\left(q_{1}-1\right)+\left(q_{2}-1\right)+$ $\left(q_{3}-1\right)+9 ;$ whence

$$
\begin{equation*}
Q_{N} / q_{1} q_{2} q_{3} \geq(a / 2)\left(a^{2} / 3\right)\left(a^{4} / 5\right)\left(a^{9} / 5^{2}\right)=a^{16} / 750 \approx 2.9 \tag{66}
\end{equation*}
$$

and we get (57).]
Lemma 24. If $N$ satisfies (52) and $k=2$, then (57) holds if $N / q_{1} q_{2} \geq$ 3 , or if at least one $q_{i} \geq 11$.
[Let $N / q_{1} q_{2}=r$. Then by (55), $Q_{N}=F_{q_{1} q_{2} r} F_{r} / F_{q_{2} r} F_{q_{1} r}$, and by (8),

$$
\begin{equation*}
Q_{N}=\sum_{h=1}^{q_{1}}\binom{q_{1}}{h} F_{q_{2} r}^{h-1} F_{q_{2} r-1}^{q_{1}-h} F_{h} / \sum_{h=1}^{q_{1}}\binom{q_{1}}{h} F_{r}^{h-1} F_{r-1}^{q_{1}-h} F_{h} \tag{67}
\end{equation*}
$$

whence, by Lemma 2, $Q_{N} \geq\left(F_{q_{2} r-1} / F_{r}\right)^{q_{1}-1}$. Thus, by (58)

$$
\begin{equation*}
Q_{N} / q_{1} q_{2} \geq\left\{a^{\left(q_{2}-1\right) r-1}\left(1-b^{\frac{( }{2}\left(q_{2} r-1\right)}\right) /\left(1+b^{2 r}\right)\right\}^{q_{1}-1} / q_{1} q_{2} \tag{68}
\end{equation*}
$$

Firsi we assume that $r \geq 3$ ．Then，by the kind of argument used above，if $q_{2} \geq 3$ and $q_{2} \geq 2$ ，and by（68），
（69）

$$
\begin{aligned}
Q_{N} / q_{1} q_{2} \geq\left(a^{q_{1}-3} / q_{1}\right)\left(a^{3 q_{2}-4} / q_{2}\right)\left\{a\left(1-b^{10}\right) /(1\right. & \left.\left.+b^{6}\right)\right\}^{q_{1}-1} \\
& >a^{4}(0.94)^{2} / 6>1
\end{aligned}
$$

Next，we assume that $q_{1} \geq 2, q_{2} \geq 11, r \geq 1$ ．Then，by（68），

$$
\begin{equation*}
\mathrm{Q}_{\mathrm{N}} / q_{1} q_{2} \geq\left(\mathrm{a}^{8 q_{1}-17} / q_{1}\right)\left(\mathrm{a}^{q_{2}-2} / q_{2}\right)\left\{a\left(1-b^{20}\right) /\left(1+b^{2}\right)\right\}^{q_{1}-1}>a^{9}(0.72) / 22>2 . \tag{70}
\end{equation*}
$$

The results（69）and（70）establish the lemma．］
Lemma 25．If $q$ is prime and $q \geq 3$ ，then there is a prime $p$ such that $\mathrm{q}=\alpha(\mathrm{p})$ 。
［If $q \geq 3, F_{q} \geq 2$ ，by Lemma 2，and so $F_{q}$ has a prime factor $p$ ．By Lem－ ma 8，$\alpha(\mathrm{p})$ divides q ，whence，since q is prime，$\alpha(\mathrm{p})=\mathrm{q}$. ］

Lemma 26．If $q$ is prime and $\lambda \geq 2$ ，then there is a prime $p \neq 5$ ， such that $\mathrm{q}^{\lambda}=\alpha(\mathrm{p})$ 。
［By Lemma 16 and Theorem 1，if $q^{\lambda-1}=m,\left(F_{q m} / F_{m}, F_{m}\right)=1$ if $q \neq 5$ ； and if $5^{\lambda-1}=m,\left(F_{5 m} / F_{m}, F_{m}\right)=5$ ．If $q \neq 5$ ，by Lemma $17, F_{q m} / F_{m} \geq$ $F_{4} / F_{2}=3$ ；so that $\mathrm{F}_{\mathrm{qm}}$ must have a prime factor $\mathrm{p} \neq 5$ ，prime to $\mathrm{F}_{\mathrm{m}}$ 。 If $q=5$ ，since $F_{25} / 5 F_{5}=3001$ ，by（2），Lemma 17 shows that again $F_{q m}$ has a prime factor $p \neq 5$ ，prime to $F_{m}$ ．Thus，by Lemma 8，for any $q, \alpha(p)$ divides $q m=q^{\lambda}$ but not $m=q^{\lambda-1}$ ．Therefore $q^{\lambda}=\alpha(p)$ ．$]$

We now have sufficient information to prove Carmichael＇s theorem．
Theorem 6。 If $N \neq 1,2,6$ ，or 12 ，then there is a prime $p$ such that $\mathrm{N}=\alpha(\mathrm{p})$ 。

Proof．Let the（unique）prime－power expansion of N be given by（52）． By Lemma 21，Lemmas 22，23，and 24 show that the theorem holds in the fol－ lowing cases：（i）if $k \geq 4$ ，all $N$ ；（ii）if $k=3$ and either（a）one $q_{i} \geq 11$ ， （b）no $q_{i}=2$ ，or（c）one $n_{i} \geq 2$ ；and（iii）if $k=2$ and either（a）$N / q_{1} q_{2}$ $\geq 3$ or（b）one $q_{1} \geq 11$ ．In addition，Lemmas 25 and 26 show that the theorem holds（iv）if $k=1$ and $N \neq 2$ ．We see from（2）that，indeed，when $N=1,2$ ，

6 , or 12 , there is no prime $p$ such that $N=\alpha(p)$. It therefore remains to show that such a $p$ exists, (v) when $k=3$, no $q_{i} \geq 11$, one $q_{i}=2$, and no $n_{i} \geq 2$, and (vi) when $k=2, N \neq 6$ or $12, N / q_{1} q_{2}=1$ or 2 , and no $q_{i}$ $\geq 11$. We look for primes $p$ which divide $F_{N}$ but no corresponding $F_{N_{(1)}}$, for then $\mathrm{N}=\alpha(\mathrm{p})$, as explained earlier.

Case (v). We have $\mathrm{N}=2 \cdot 3 \cdot 5=30,2 \cdot 3 \cdot 7=42$, and $2 \cdot 5 \cdot 7=$ 70. We see from (2) that $30=\alpha(31), 42=\alpha(211)$, and $70=\alpha(71)=\alpha(911)$; so that the theorem holds.

Case (vi). We have $N=2 \cdot 5=10,2^{2} \cdot 5=20,2^{\circ} 7=14,2^{2} \circ 7=28$, $3 \cdot 5=15,3 \cdot 7=21$, and $5 \cdot 7=35$. We see from (2) that $10=\alpha(11)$, $20=\alpha(41), 14=\alpha(29), 28=\alpha(281), \quad 15=\alpha(61), \quad 21=\alpha(421)$, and $35=$ $\alpha(141961)$. This completes the theorem.

Lemma 27。 If $\mathrm{N}=\alpha(\mathrm{p})$ and $\mathrm{N} \neq 5$ whence $\mathrm{p} \neq 5), \mathrm{p}$ is a simple prime factor of $\mathrm{F}_{\mathrm{N}}$.
[ By Lemma 18, if $p$ is a mpf of $\mathrm{F}_{\mathrm{N}}$, p divides both N and $\mathrm{F}_{\mathrm{N}^{\circ}}$ Thus, since, by Theorem 1, if $p \neq 5,(p, \alpha(p))=1$; $N$ must be divisible by $p \alpha(p)$, so that $\mathrm{N} \neq \alpha(\mathrm{p})$. The lemma follows.]

By Lemma 27, Theorem 5 is seen to follow from Theorem 6. We also see that Theorem 3 and its corollaries follow from Theorems 1, 2, and 6 (with the exception of the fact that the $\ell_{S}(m, p)$ increase with $\left.s\right)$.

For completeness, we also state the following result.
Lemma 28。 If $f_{1}=1, f_{2}, f_{3}, \cdots, f_{m}=N$ are all the divisors of $N$, then

$$
\begin{equation*}
\mathrm{F}_{\mathrm{N}}=\prod_{\mathrm{r}=1}^{\mathrm{m}} \mathrm{Q}_{\mathrm{f}_{\mathrm{r}}} \tag{71}
\end{equation*}
$$

[If $N$ satisfies (52), its divisors are the $\left(n_{1}+1\right)\left(n_{2}+1\right) \cdots\left(n_{k}+1\right)=m$ integers

$$
\mathrm{f}=q_{1}^{s_{1}} q_{2}^{\mathrm{s}_{2}} \ldots q_{k}^{\mathrm{s}_{\mathrm{k}}}
$$

where $0 \leq s_{i} \leq n_{i}, i=1,2, \cdots, k_{0}$ By (55), a particular factor $F_{g}$ can appear only once in $\mathrm{Q}_{\mathrm{f}}$; and this, when

$$
g=q_{1}^{t_{1}} q_{2}^{t_{2}} \cdots q_{k}^{t_{k}}
$$

and $t_{i}=n_{i}$ except when $i=i_{1}, i_{2}, \cdots, i_{h}$ (when $t_{i}<n_{i}$ ), only if $f=g$ or $g q_{i_{1}}$ or $g q_{i_{1}} q_{i_{2}}$ or $\cdots$ or $g q_{i_{1}} q_{i_{2}} \cdots q_{i_{h}}$. It follows by (55) that $F_{g}$ appears in

to the total power

$$
1-\binom{h}{i}+\binom{h}{2}-\cdots+(-1)^{h}\binom{h}{h}=(1-1)^{h}=0 \text { if } h \geq 1
$$

and 1 if $h=0$ 。 This proves that the product is simply $\left.F_{N}{ }^{\circ}\right]$

## 5. PERIODICITY OF RESIDUES

We shall complete this discussion of divisibility properties with a survey of results pertaining to the characteristic number $\mu(\mathrm{m}, \mathrm{n})$ defined inSection 1.

Lemmas 13 and 14 show that we may limit the study of the functions $\alpha(\mathrm{m}, \mathrm{n})$ and $\mu(\mathrm{m}, \mathrm{n})$ to that of $\alpha(\mathrm{p}, \mathrm{n})$ and $\mu(\mathrm{p}, \mathrm{n})$, where p is prime. We have established the essential properties of $\alpha(\mathrm{p}, \mathrm{n})$ in Theorem 1. Thus, by (15), the corresponding behaviour of $\mu(\mathrm{p}, \mathrm{n})$ is known if we know that of $\beta(\mathrm{p}, \mathrm{n})$. So far, we have only stated, in Lemma 10, that $\beta(\mathrm{m})$ (and, in particular, $\beta(\mathrm{p}, \mathrm{n})$ ) is always an integer. The papers of Robinson [5], Vinson [6], and Wall [7] have answered almost every question that may be asked about $\beta(\mathrm{p}, \mathrm{n})$, andit is their work which will be outlined here. Proofs of all the results quoted below may be found in Vinson's paper [6], and so will be omitted here.

Theorem 7. If $p$ is an odd prime and $n$ a positive integer, then

$$
\beta(\mathrm{p}, \mathrm{n})=\left\{\begin{array}{l}
4 \text { if } \operatorname{pot}_{2} \alpha(\mathrm{p})=0  \tag{72}\\
1 \text { if } \operatorname{pot}_{2} \alpha(\mathrm{p})=1 \\
2 \text { if } \operatorname{pot}_{2} \alpha(\mathrm{p}) \geq 2
\end{array}\right\}
$$

but

$$
\begin{equation*}
\beta(2,1)=\beta(2,2)=1, \quad \text { and } \quad \beta(2, \mathrm{n})=2 \text { if } \mathrm{n} \geq 3 \tag{73}
\end{equation*}
$$

We note that，with the two exceptions given in（75），$\beta(\mathrm{p}, \mathrm{n})$ is independ－ ent of $n$ ．Also，$\beta(\mathrm{p}, \mathrm{n})$ always takes one of the three values 1,2 ，or 4 － a remarkably simple result．

Theorem 8．If $m$ is a positive integer satisfying（27），then（i）$\beta(\mathrm{m})=$ 4，if $m \geq 3$ and $\alpha(\mathrm{m})$ is odd；（ii）$\beta(\mathrm{m})=1$ ，if $\operatorname{pot}_{2} \alpha\left(\mathrm{p}_{\mathrm{i}}\right)=1$ for every $p_{i} \neq 2(i=1,2, \cdots, k)$ and if $\operatorname{pot}_{2} m \leq 2$ ；and（iii）$\beta(m)=2$ for all other m。

We note that Theorem 8 contains Theorem 7，as a special case，when $\mathrm{m}=\mathrm{p}^{\mathrm{n}}$ ，where p is prime。（The connection is through Lemma 13。）

Theorem 9。 If $p$ is an odd prime，not equal to 5 ，and $n$ a positive integer，then

$$
\beta(\mathrm{p}, \mathrm{n})=\left\{\begin{array}{lllll}
1 & \text { if } \mathrm{p} \equiv 11 & \text { or } & 19 & (\bmod 20)  \tag{74}\\
2 & \text { if } \mathrm{p} \equiv 3 & \text { or } & 7 & (\bmod 20) \\
4 & \text { if } \mathrm{p} \equiv 13 & \text { or } & 17 & (\bmod 20)
\end{array}\right\}
$$

and（of the remaining values of $\mathrm{p} \equiv 1$ or $9(\bmod 20)) \beta(\mathrm{p}, \mathrm{n}) \neq 2$ if $\mathrm{p} \equiv 21$ or $29(\bmod 40)$ 。

These results are connected with the foregoing by way of Lemma 12 。 Vinson points out that the theorem is＂complete＂in the sense that every re－ maining possibility occurs；he lists the examples：
（75）

$$
\left\{\begin{aligned}
\beta(521)=1, \beta(41)=2, \beta(761)=4, & {[p \equiv 1(\bmod 40)] } \\
\beta(809)=1, \beta(409)=2, \beta(89)=4, & {[p \equiv 9(\bmod 40)] } \\
\beta(101)=1, \beta(61)=4, & {[p \equiv 21(\bmod 40)] } \\
\beta(29)=1, \beta(109)=4, & {[p \equiv 29(\bmod 40)] }
\end{aligned}\right.
$$

 ASSOCIATED WITH A GENERALIZED PASCAL TRIANGLEV.C. Harris and Carolyn C. Styles, San Diego State College \& San Diego Mesa College

## 1. INTRODUCTION

In this paper we introduce the numbers

$$
\left\{\begin{array}{l}
\left.u_{n}=u_{n}(p, q, s)=\sum_{i=0}^{\left[\frac{n}{p+s q}\right.}\right]\left(\left[\begin{array}{c}
\left.\frac{n-i p}{s}\right] \\
i
\end{array}\right] \quad n=1,2, \ldots\right.  \tag{1.1}\\
u_{0}=u_{0}(p, q, s)=1
\end{array}\right.
$$

where $n, p, q$, $s$ are positive integers and $[x]$ is the largest integer in $x$. The characteristic equation and a generating function are developed and the relation to a generalized Pascal's triangle is exhibited in Section 2. An interesting feature is the repetition of each term $g$ times where $g=(p, s)$. Certain sums and some properties relating to congruence are established in Sections 3 and 4.

The numbers corresponding to the case $s=1$ are developed in our previous paper [2]. Thus the Fibonacci numbers are those for $p=q=s=1$. The numbers in Dickinson [1] are the special case $p=a, q=1, s=c-a$. By multiplying the binomial coefficients

$$
\binom{\left[\frac{n-i p}{s}\right]}{i}
$$

by $\mathrm{a}^{\mathrm{n}-\mathrm{i} q_{\mathrm{b}} \mathrm{iq}}{ }^{*}$ before summing, the numbers could be generalized further.
*A more appropriate choice of exponents, suggested by Dr. David Zeitlin, appears in a paper by him which will follow.

## 2. THE CHARACTERISTIC EQUATION AND GENERATING FUNCTION

We note that
or zero, from properties of binomial coefficients. Hence, if $E f(x)=f(x+1)$ we have $\left(E^{S}-1\right) u_{n}$ is a sum of binomial coefficients with first coefficient involving iq -1 . After repeating $q$ times there results

$$
\left(E^{s}-1\right)^{q} u_{n}(p, q, s)=u_{n-p}(p, q, s), n-p \geq 0
$$

or
(2.1) $u_{n+p+q s}=\binom{q}{1} u_{n+p+(q-1) s}-\binom{q}{2} u_{n+p+(q-2) s}+\cdots+(-1)^{q+1} u_{n+p}+u_{n}$

Hence the characteristic equation is

$$
\begin{equation*}
x^{p}\left(x^{s}-1\right)^{q}-1=0 \tag{2.2}
\end{equation*}
$$

with initial conditions

$$
\begin{equation*}
u_{0}=u_{1}=\cdots=u_{p+q s-1}=1 \tag{2.3}
\end{equation*}
$$

It may be remarked that $u_{p+q s}=2$.
Suppose the arithmetic triangle to be written but with each row repeated $s$ times. Then one sees that $u_{n}(p, q, s)$ is the sum of the term in the first column and $\mathrm{n}^{\text {th }}$ row (counting the top row as the zero ${ }^{\text {th }}$ row) and the terms obtained by starting from this term and taking steps $p, q$ - that is, $p$ units up and $q$ units to the right.

When $(p, s)=g>1$ the sequences $\left\{u_{n g}\right\},\left\{u_{n g+1}\right\}, \cdots,\left\{u_{n g+(g-1)}\right\}$
are the same since each sequence is determined by the same recursion formula and the same initial conditions.

Let $f(x)=x^{p}\left(x^{s}-1\right)^{q}-1$ so that $f^{\prime}(x)=x^{p-1}\left(x^{s}-1\right)^{q-1}\left[(p+q s) x^{s}-p\right]$. The roots of $f^{\prime}(x)=0$ are the roots of

$$
x=0, \quad x^{s}=1 \quad \text { and } \quad x^{s}=\frac{p}{p+q s}
$$

None of the roots of $f^{\prime}(x)=0$ is a root of $f(x)=0$ and $f(x)$ has no multiple root. If the $p+s q$ roots of $f(x)$ are $x_{1}, x_{2}, x_{3}, \cdots, x_{p+s q}$ then the determinant of the coefficients $c_{1}, c_{2}, \cdots, c_{p+q s}$ in

$$
\sum_{i=1}^{p+q s} c_{i} x_{i}^{n+1}=u_{n} \quad n=0,1, \cdots, p+s q-1
$$

is different from zero. The system can be solved by Cramer's rule using Vandermondians. It results that $c_{i}=\left(x_{i}^{S}-1\right) /\left[\left(x_{i}-1\right)\left\{[p+s q] x_{i}^{s}-p\right\}\right]$ and hence

$$
\begin{equation*}
u_{n}=\sum_{i=1}^{p+s q} \frac{\left(x_{i}^{s}-1\right) x_{i}^{n+1}}{\left(x_{i}-1\right)\left[(p+s q) x_{i}^{S}-p\right]}, n=0,1,2, \cdots \tag{2.4}
\end{equation*}
$$

To obtain a generating function, write

$$
S=\sum_{i=0}^{\infty} u_{i} x^{i}
$$

Then by multiplying $S$ by each of

$$
(-1)\binom{q}{1} x^{s},(-1)^{2}\binom{q}{2} x^{2 s}, \cdots,(-1)^{q}\binom{q}{q} x^{q s} \quad \text { and } \quad-x^{p+q s}
$$

and adding, one finds

$$
\left[\left(1-x^{s}\right)^{q}-x^{p+s q}\right] S=\sum_{k=0}^{q-1} \sum_{i=0}^{s-1} \sum_{j=0}^{k}(-1)^{j}\binom{q}{j} x^{k s+i}
$$

Note we have used $\dot{u}_{0}=u_{1}=\cdots=u_{p+s q-1}=1$ and (2.1). Hence

$$
\sum_{n=0}^{\infty} u_{n} x^{n}=\frac{\sum_{k=0}^{q-1} \sum_{i-0}^{s-1} \sum_{j=0}^{k}(-1)^{j}\binom{q}{j} x^{k s+i}}{\left(1-x^{s}\right)^{q}-x^{p+s q}}
$$

The numerator is equal to

$$
\begin{aligned}
\sum_{i=0}^{S-1} x^{i}\left\{\sum_{k=0}^{q-1}(-1)^{k}\binom{q-1}{k}\left(x^{S}\right)^{k}\right\} & =\sum_{i=0}^{S-1} x^{i}\left(1-x^{S}\right)^{q-1} \\
& =\left(1-x^{S}\right)^{q} /(1-x)
\end{aligned}
$$

Hence

$$
\begin{equation*}
\sum_{n=0}^{\infty} u_{n} x^{n}=\frac{\left(1-x^{s}\right)^{q} /(1-x)}{\left(1-x^{s}\right)^{q}-x^{p+s q}} \tag{2.5}
\end{equation*}
$$

As an example, for $p=2, q=2, s=3$, this gives

$$
\sum_{n=\theta}^{\infty} u_{n}(2,2,3) x^{n}=\frac{1+x+x^{2}-x^{3}-x^{4}-x^{5}}{1-2 x^{3}+x^{6}-x^{8}}
$$

This gives the sequence
$\left\{u_{n}(2,2,3)\right\}=1,1,1,1,1,1,1,1,2,2,2,4,4,4,7,7,8,12,12,16,21,21,31,37, \cdots$
3. SUMS
(3.1)

$$
\begin{aligned}
\sum_{i=0}^{n} u_{i}= & \sum_{i=0}^{q-1}\left\{( - 1 ) ^ { i } ( \begin{array} { c } 
{ q - 1 } \\
{ i }
\end{array} ) \left[u_{n+p+s(q-i)}+\right.\right. \\
& \left.\left.u_{n+p+s(q-i)-1}+\cdots+u_{n+p+s(q-i)-s+1}\right]\right\}-s \delta_{1 q}
\end{aligned}
$$

where $\delta_{i j}$ is Kronecker's $\delta$.

This is seen to be true for $q=1$ and all $n$ by summing $u_{0}=u_{p+s}-$ $u_{p} ; u_{1}=u_{p+s+1}-u_{p+1} ; \cdots ; u_{n}=u_{p+s+n}-u_{p+n^{0}}$ Since $u_{0}=u_{1}=\cdots=$ $u_{p+s q-1}=1$, this gives

$$
\sum_{i=0}^{n} u_{i}=\sum_{i=0}^{n+p+s} u_{i}-(p+s)-\sum_{i=0}^{n+p} u_{i}+p
$$

which is the result. Also this is true for $n=0$ and all $q$. We have to show

$$
u_{0}=\sum_{i=0}^{q-1}(-1)^{i}\binom{q-1}{i}\left[u_{p+s(q-i)}+\cdots+u_{p+s(q-i)-(s-1)}\right]
$$

But $u_{p+s q}=2$ so that by separating the term corresponding to $i=0$ we get $1+s(1-1)^{q-1}=1=u_{0}$.

It remains to show the result in general. Assume (3.1) to be true for $\mathrm{q} \geq 2$ and $\mathrm{n}=\mathrm{k}$; then

$$
\begin{aligned}
\sum_{i=0}^{k+1} u_{i}= & u_{k+1}+\sum_{i=0}^{k} u_{i}=\sum_{i=0}^{q}(-1)^{i}\binom{q}{i} u_{k+p+(q-i) s+1}+ \\
& \sum_{i=0}^{q-1}(-1)^{i}\binom{q-1}{i}\left[u_{k+p+s(q-i)}\right.
\end{aligned} \begin{aligned}
& u_{k+p+s(q-i)-1}+\cdots \\
& \left.+u_{k+p+s(q-i)-s+1}\right]
\end{aligned}
$$

By combining terms

$$
u_{k+1+p+s(q-i)}=u_{k+p+s(q-i)+1}
$$

using

$$
\binom{q}{j}-\binom{q-1}{j-1}=\binom{q-1}{j}
$$

the result follows and the theorem is proved.
$\sum_{i=0}^{n}(-1)^{n-i} u_{i}=\left\{\begin{array}{l}\sum_{k=0}^{q} \sum_{i=n+1}^{n+p+s(q-k)}(-1)^{n+p+s(q-k)+k-i}\binom{q}{k} u_{i}, s \text { even } \\ \frac{1}{1-(-1)^{p+s q_{2} q}}\left[\sum_{k=0}^{q} \sum_{i=n+1}^{n+p+s(q-k)}(-1)^{n+p+s(q-k)+k-i}\binom{q}{k} u_{i}+\right.\end{array}\right.$

$$
+\left\{\begin{array}{ccc}
0 & p \equiv q \equiv 1 & (\bmod 2)  \tag{3.2}\\
(-1)^{n+1} & 2^{q-1} & p \equiv q \equiv 0 \\
(-1)^{n} & 2^{q-1} & p \neq q \\
(\bmod 2) & (\bmod 2)
\end{array}\right] \text { s odd }
$$

Proof: Solve (2.1) for $u_{n}$ and write $(-1)^{n-i} u_{i}$ for $i=n, n-1, \cdots, 0$. The sum of the $(k+1)$ st column formed by the expansions is

$$
\begin{aligned}
& \sum_{i=0}^{n}(-1)^{k+i}\binom{q}{k} u_{n+p+s(q-k)-i}=\sum_{i=0}^{n+p+s(q-k)}(-1)^{n+p+s(q-k)-i+k}\binom{q}{k} u_{i} \\
&-(-1)^{k+n+1}\binom{q}{k}\left[1-1+\cdots+(-1)^{p+s(q-k)-1}\right]
\end{aligned}
$$

since the terms added to obtain the sum on the right have $u_{i} \equiv 1$ in each case. Hence this gives

$$
\begin{aligned}
\sum_{i=0}^{n}(-1)^{k+i}\binom{q}{k} u_{n+p+s(q-k)-i}=\sum_{i=0}^{n+p+s(q-k)}(-1)^{n+p+s(q-k)+k-i}\binom{q}{k} u_{i} \\
+(-1)^{n+k}\binom{q}{k} \cdot \epsilon
\end{aligned}
$$

where $\epsilon=0, \mathrm{p}+\mathrm{s}(\mathrm{q}-\mathrm{k}) \equiv 0(\bmod 2)$ and $=1$ otherwise.
$\sum_{i=0}^{n}(-1)^{n-i} u_{i}=\sum_{k=0}^{q} \sum_{i=n+1}^{n+p+s(q-k)}(-1)^{n+p+s(q-k)+k-i}\binom{q}{k} u_{i}$

$$
\begin{gathered}
+\sum_{k=0}^{q} \sum_{i=0}^{n}(-1)^{n+p+s(q-k)+k-1}\binom{q}{k} u_{i}+ \\
\sum_{k=0}^{q}(-1)^{n+k}\binom{q}{k} \epsilon(k), p+s(q-k) \neq 0(\bmod 2) \\
0 \quad, p+s(q-k) \equiv 0(\bmod 2)
\end{gathered}
$$

But
$\sum_{k=0}^{q} \sum_{i=0}^{n}(-1)^{n+p+s(q-k)+k-i}\binom{q}{k} u_{i}=$

$$
\begin{cases}0, & s \equiv 0(\bmod 2) \\ (-1)^{p+s q} 2^{q} \sum_{i=0}^{n}(-1)^{n-i} u_{i}, s \equiv 1(\bmod 2)\end{cases}
$$

and
$\sum_{n=0}^{q}(-1)^{n+k}\binom{q}{k} \in(p, q, s, k)=$

$$
\left\{\begin{array}{cl}
(-1)^{\mathrm{n}+1} 2^{\mathrm{q}-1}, & \text { s odd } \mathrm{p} \equiv \mathrm{q} \equiv 0(\bmod 2) \\
(-1)^{\mathrm{n}} 2^{\mathrm{q}-1} & , \text { s odd } \mathrm{p} \neq \mathrm{q} \quad(\bmod 2) \\
0, & \text { otherwise }
\end{array}\right.
$$

Combining these results gives the theorem.

It may be remarked that

$$
\sum_{i=0}^{n} u_{2 i} \text { and } \sum_{i=0}^{n} u_{2 i+1}
$$

can be obtained from (3.1) and (3.2).

## 4. DIVISIBILITY PROPERTIES

Using methods similar to those of our previous paper, one can show the following: Any $p+s q$ consecutive terms are relatively prime。 The least nonnegative residues modulo any positive integer $m$ of $u_{n}(p, q, s)$ are periodic with a period $P$ not exceeding $\mathrm{m}^{\mathrm{p}+\mathrm{Sq}}$. There is no preperiod and each period begins with $p+s q$ terms all unity. Any prime divides infinitely many $u_{n}(p, q, s)$ since

$$
u_{P-p} \equiv \sum_{i=0}^{q}(-1)^{i}\binom{q}{i} u_{P+s(q-i)} \equiv 0(\bmod m) .
$$

## ADVANCED PROBLEMS AND SOLUTIONS

Edited by V.E. Hoggatt, Jr., San Jose State College, San Jose, Calif.

Send all communications concerning Advanced Problems and Solutions to Verner E. Hoggatt, Jr. , Mathematics Department, San Jose State College, San Jose, California. This department especially welcomes problems believed to be new or extending old results. Proposers should submit solutions or other information that will assist the editor. To facilitate their consideration, solutions should be submitted on separate signed sheets within three months after publication of the problems.

H-89. Proposed by Maxey Brooke, Sweeny, Texas.
Fibonacci started out with a pair of rabbits, a male and a female。 A female will begin bearing after two months and will bear monthly thereafter. The first litter a female bears is twin males, thereafter she alternately bears female and male.

Find a recurrence relation for the number of males and females born at the end of the $n^{\text {th }}$ month and the total rabbit population at that time.

H-90 Proposed by V. E. Hoggaff, Jr., San Jose State College, San Jose, Calif.
Let the total population after $n$ time periods be the sequence $\left\{F_{n}^{3}\right\}_{n=2}^{\infty}$ determine the common birth sequence for every female rabbit and tie it in with the value of the Fibonacci polynomials at $x=2, \quad\left(f_{0}(x)=0, f_{1}(x)=1\right.$ and $\left.f_{n+2}(x)=x f_{n+1}(x)+f_{n}(x) ; n \geq 0\right)$ 。

## H-91 Proposed by Douglas Lind, University of Virginia, Charlotresville, Va.

Let $m=\left[\frac{k}{2}\right]$, then show

$$
F_{k n} / F_{n}=\sum_{j=0}^{m=1}(-1)^{j n} L_{k-1-2 j}+e_{n}
$$

where

$$
e_{n}=\left\{\begin{array}{cl}
(-1)^{m n} & \text { if } k \text { is odd } \\
0 & \text { if } k \text { is even }
\end{array}\right.
$$

and $[\mathrm{x}]$ is the greatest integer not exceeding x 。

H-92 Proposed by Brother U. Alfred, St. Mary's College, Calif.
Prove or Disprove: A part from $\mathrm{F}_{1}, \mathrm{~F}_{2}, \mathrm{~F}_{3}, \mathrm{~F}_{4}$, no Fibonacci number, $F_{i}(i>0)$ is a divisor of a Lucas Number.

H-93 Proposed by Douglas Lind, University of Virginia, Charlottesville, Va.
Show that

$$
\begin{aligned}
& F_{n}=\sum_{k=1}^{\overline{n-1}}\left(3+2 \cos \frac{2 k \pi}{n}\right) \\
& L_{n}=\sum_{k=1}^{\overline{n-2}}\left(3+2 \cos \frac{(2 k+1) \pi}{n}\right)
\end{aligned}
$$

where $\overline{\mathrm{n}}$ is the greatest integer contained in $\mathrm{n} / 2$.

## SOLUTIONS

H-50 Proposed by Ralph Greenberg, Philadelphia, Pa. and H. Winthrop, University of So.
Florida, Tampa, Fla.
Show

$$
\sum_{n_{1}+n_{2}+n_{3}+\cdots+n_{i}=n} \Pi n_{i}=F_{2 n}
$$

where the sum is taken over all partitions of $n$ into positive integers and the order of distinct summands is considered.

A paper by D。A。Lind and V．E．Hoggatt，Jr．，＂Composition Formulas Derived from Birth Sequences，＂will appear soon in the Fibonacci Quarterly，and will discuss this among many other examples．

## H－22 Proposed by V．E．Hoggatt，Jr．，San Jose Staie College，San Jose，Calif．

If

$$
P(x)=\prod_{i=1}^{\infty}\left(1+x^{F_{i}}\right)=\sum_{n=0}^{\infty} R(n) x^{n}
$$

then show
（i）$\quad \mathrm{R}\left(\mathrm{F}_{2 \mathrm{n}}-1\right)=\mathrm{n}$
（ii）$\quad R(N)>n$ if $N>F_{2 n}-1$ ．

H－53 Proposed by V．E．Hoggaff，Jr．，San Jose State College，San Jose，Calif．
and S．L．Basin，Sylvania Electronics Systems，Mt．View，Calif．
The Lucas sequence $L_{1}=1, L_{2}=3 ; L_{n+2}=L_{n+1}+L_{n}$ for $n \quad 1$ is incomplete（see V．E．Hoggatt，Jr．and C．King，Problem E－1424 American Monthly，Vol。67，No．6，June－July 1960，p．593，since every integer nis not the sum of distinct Lucas numbers．OBSERVE THAT 2，6，9，13，17，$\cdots$ cannot be so represented．Let $M(n)$ be the number of positive integers less than n which cannot be so represented．Show

$$
M\left(L_{n}\right)=F_{n-1}
$$

Find，if possible，a closed form solution for $M(n)$ ．

A paper by David Klarner to appear soon in the Fibonacci Quarterly com－ pletely answers these questions．

Let $F(n)$ and $L(n)$ denote the $n^{\text {th }}$ Fibonacci and $n^{\text {th }}$ Lucas numbers, respectively.

Given $U(n)=F(F(n)), V(n)=F(L(n)), W(n)=L(L(n))$ and $X(n)=L\left(F_{n}\right)$, find recurrence relations for the sequences $U(n), V(n), W(n)$, and $X(n)$.

A paper by student Gary Ford to appear soon in the Fibonacci Quarterly offers several answers to this problem. Also a paper by R. Whitney deals with this and will appear shortly.
H-52 Proposed by Brother U. Alfred, St. Mary's College, Calif.

Prove that the value of the determinant

$$
\left|\begin{array}{ccc}
u_{n}^{2} & u_{n+2}^{2} & u_{n+4}^{2} \\
u_{n+2}^{2} & u_{n+4}^{2} & u_{n+6}^{2} \\
u_{n+4}^{2} & u_{n+6}^{2} & u_{n+8}^{2}
\end{array}\right|
$$

is $18(-1)^{\mathrm{n}+1}$.

Solution by V. E. Hoggatt, Jr., San Jose State College, San Jose, Calif.

Since $F_{2 n}^{2}=\left(L_{4 n}-2\right) / 5$, the auxiliary polynomial satisfied by $F_{2 n}^{2}$ is the product of the auxiliary polynomials for $L_{4 n}:\left(x^{2}-7 x+1\right)$ and for $C_{n}=-2$ : ( $\mathrm{x}-1$ ) or

$$
\left(x^{2}-7 x+1\right)(x-1)=x^{3}-8 x^{2}+8 x-1
$$

Therefore the recurrence relation for $F_{2 n}^{2}$ is

$$
u_{n+6}^{2}=8 u_{n+4}^{2}-8 u_{n+2}^{2}+u_{n}^{2}
$$

Thus $D_{n+1}=(-1) D_{n}$ by using the above recurrence relation after multiplying the first column of $D_{n}$ by -1 . The value of $D_{0}$ is -18 , therefore $D_{n}=18(-1)^{n+1}$.

## TWO BEAUTIES

H-47 Proposed by L. Carlitz, Duke University, Durham, N.C.

Show that

$$
\sum_{n=0}^{\infty}\binom{n+k-1}{n} L_{n} x^{n}=\frac{\psi_{k}(x)}{\left(1-x-x^{2}\right) k}
$$

where

$$
\psi_{k}(x)=\sum_{r=0}^{k}(-1)^{r}\binom{k}{r} L_{r} x^{r}
$$

## H-51 Proposed by V. E. Hoggaff, Jr., San Jose Stafe College, San Jose, Calif.

 and L. Carlitz, Duke University, Durham, N.C.Show that if
(i)

$$
\frac{x t}{1-(2-x) t+\left(1-x-x^{2}\right) t^{2}}=\sum_{k=1}^{\infty} Q_{k}(x) t^{k}
$$

and
(ii)

$$
\sum_{n=0}^{\infty}\binom{n+k-1}{n} F_{n} x^{n}=\frac{\phi_{k}(x)}{\left(1-x-x^{2}\right)^{k}}
$$

that

$$
\phi_{k}(x)=\sum_{r=0}^{k}(-1)^{r+1}\binom{k}{r} F_{r} x^{r}=Q_{k}(x)
$$

Solutions by Kathleen Weland, Gary Ford, and Douglas Lind, Undergraduate Research Program, University of Sanfa Clara, Sanfa Clara, Calif.

It is familiar that

$$
(1-x)^{-k}=\sum_{n=0}^{\infty}\binom{n+k-1}{n} x^{n} .
$$

Let $\mathrm{W}_{\mathrm{n}}$ obey $\mathrm{W}_{\mathrm{n}+2}=\mathrm{p} \mathrm{W}_{\mathrm{n}+1}-\mathrm{qW} \mathrm{n}_{\mathrm{n}}, \mathrm{p}^{2}-4 \mathrm{q} \neq 0$, and let $\mathrm{a}=\mathrm{b}$ both satisfy $x^{2}-p x+q=0$, so that $a+b=p, a b=q$. Then $W_{n}=A a^{n}+B b^{n}$ for some constants $A$ and $B$ and all $n$. It follows that

$$
\begin{aligned}
\sum_{n=0}^{\infty}\binom{n+k-1}{n} W_{n} x^{n} & =A(1-a x)^{-k}+B(1-b x)^{-k} \\
& =\frac{A(1-b x)^{k}+B(1-a x)^{k}}{\left(1-p x+q x^{2}\right)^{k}} \\
& =\frac{\left[A \sum_{j=0}^{k}(-1)^{j}\binom{k}{j} b^{j} x^{j}+B \sum_{j=0}^{k}(-1)^{j}\binom{k}{j} a^{j}\right]}{\left(1-p x+q x^{2}\right)^{k}} \\
& =\frac{\left[\sum_{-j=0}^{k}(-1)^{j}\binom{k}{j}\left(A a^{-j}+B b^{-j}\right)(a b x)^{j}\right]}{\left(1-p x+q x^{2}\right)^{k}} \\
& =\frac{\left[\sum_{-j=0}^{k}(-q)^{j}\binom{k}{j} W_{-j} x^{j}\right]}{\left(1-p x+q x^{2}\right)^{k}}=\frac{-R_{k}(x)}{\left(1-p x+q x^{2}\right)^{k}}
\end{aligned}
$$

To get (ii) of $\mathrm{H}-51$ we put $\mathrm{p}=1, \mathrm{q}=-1, \mathrm{~W}_{\mathrm{n}}=\mathrm{F}_{\mathrm{n}}$, and recalling $\mathrm{F}_{-\mathrm{n}}=(-1)^{\mathrm{n}+1} \mathrm{~F}_{\mathrm{n}}$ we have

$$
\sum_{n=0}^{\infty}\binom{n+k-1}{n} F_{n} x^{n}=\left[\sum_{j=0}^{k}(-1)^{j+1}\binom{k}{j} F_{j} x^{j}\right]\left(1-x-x^{2}\right)^{k}
$$

To obtain $H-47$, we set $p=1, q=-1, W_{n}=L_{n}$, and remembering that $L_{-n}$ $=(-1)^{n^{2}} L_{\mathrm{n}}$ we find

$$
\sum_{n=0}^{\infty}\binom{n+k-1}{n} L_{n} x^{n}=\left[\sum_{j=0}^{k}(-1)^{j}\binom{k}{j} L_{j} x^{j}\right] \quad\left(1-x-x^{2}\right)^{k}
$$

We now generalize (i) of $\mathrm{H}-51$ 。 Since

$$
\begin{aligned}
R_{k}(x) & =\sum_{j=0}^{k}(-q)^{j}\binom{k}{j} W_{-j} x^{j} \\
& =A(1-b x)^{k}+B(1-a x)^{k}
\end{aligned}
$$

we have

$$
\begin{aligned}
\sum_{k=0}^{\infty} R_{k}(x) t^{k} & =A \sum_{k=0}^{\infty}[(1-b x) t]^{k}+B \sum_{k=0}^{\infty}[(1-a x) t]^{k} \\
& =\frac{A}{1-(1-b x) t}+\frac{B}{1-(1-a x) t} \\
& =\frac{A+B-(A+B) t+(A a+B b) x^{t}}{1-(2-p x) t+\left(1-p x+q x^{2}\right) t^{2}}
\end{aligned}
$$

Now $\mathrm{W}_{0}=\mathrm{A}+\mathrm{B}, \quad \mathrm{W}_{1}=\mathrm{Aa}+\mathrm{Bb}$, so we may write
(*) $\sum_{k=0}^{\infty} R_{k}(x) t^{k}=\frac{W_{0}+\left(x W_{1}-W_{0}\right) t}{1-(2-p x) t+\left(1-p x+q x^{2}\right) t^{2}}$

Putting $p=1, q=-1, \quad W_{n}=F_{n}$ makes $R_{k}(x)=Q_{k}(x)$ of Problem $H-51$, and (*) becomes

$$
\sum_{k=0}^{\infty} Q_{k}(x) t^{k}=\frac{x t}{1-(2-x) t+\left(1-x-x^{2}\right) t^{2}}
$$

the required result.

## Also solved by the proposers.

## LATE PROBLEM A.DDITIONS

A SIMPLE PROOF, PLEASE:
H-94 Submitted by RobertW. Floyd, Carnegie Institute of Technology, and Donald E. Knuth, California Institute of Technology.
Let $\alpha$ be any irrational number, and let the notation $\{x\}$ stand for the fractional part of x . Suppose a man has accurately marked off the points 1 , $0,\{\alpha\},\{2 \alpha\}, \cdots,\{(\mathrm{n}-1) \alpha\}$ on a line, $\mathrm{n} \geq 1$. These $\mathrm{n}+1$ points divide the line segment between 0 and 1 into $n$ disjoint intervals. Show that when the man adds the next point $\{n \alpha\}$, it falls in the largest of these $n$ intervals; if there are several intervals which have the maximum length, the point $\{n \alpha\}$ falls in one of these maximal intervals. Furthermore, if $\alpha$ is the "golden ratio" $\phi^{-1}=\frac{1}{2}(\sqrt{5}-1)=0.618 \cdots$, then the point $\{n \alpha\}$ always divides the corresponding interval into two intervals whose lengths are in the golden ratio. A number $\alpha$ has the property that $\{n \alpha\}$ always divides its interval into two parts, such that the ratio of longer to shorter is less than 2, if and only if $\{\alpha\}$ $=\phi^{-1}$ or $\phi^{-2}$. (Note: The fact that the fractional parts $\{n \alpha\}$ are asymptotically equidistributed in $(0,1)$ is well known; this problem shows the mechanism behind that theorem, since $\{n \alpha\}$ always chooses the largest remaining open place. Furthermore, the sequence $\{n \phi\}$ is the "most equidistributed" of all these sequences.)
H-95 Proposed by J. A. H. Hunter, Toronto, Canada.
Show

$$
\mathrm{F}_{\mathrm{n}+\mathrm{k}}^{3}+(-1)^{\mathrm{k}} \mathrm{~F}_{\mathrm{n}-\mathrm{k}}^{3}=\mathrm{L}_{\mathrm{k}}\left[\mathrm{~F}_{\mathrm{k}}^{2} \mathrm{~F}_{3 \mathrm{n}}+(-1)^{\mathrm{k}} \mathrm{~F}_{\mathrm{n}}^{3}\right]
$$

# A SINGULAR FIBONACCI MATRIX AND ITS RELATED LAMBDA FUNCTION 

Curtis McKnight (student) \& Dean Priest, Harding College, Searcy, Arkansas

After a very brief introduction to some of the extremely basic properties of Fibonacci numbers, a student of mine inductively produced the following identities concerning determinants of Fibonacci matrices:
(1) $\quad\left|\begin{array}{cc}F_{n} & F_{n+1} \\ F_{n+S+2} & F_{n+\mathrm{S}+3}\end{array}\right|=(-1)^{\mathrm{n}+1} \mathrm{~F}_{\mathrm{S}+2}$

$$
\left|\begin{array}{cc}
F_{n} & F_{n+m+1}  \tag{2}\\
F_{n+m+2} & F_{n+2 m+3}
\end{array}\right|=(-1)^{n+1} F_{m+1} F_{m+2}
$$

$$
\left|\begin{array}{cc}
F_{n} & F_{n+m+1}  \tag{3}\\
F_{n+m+s+2} & F_{n+2 m+s+3}
\end{array}\right|=(-1)^{n+1} F_{m+1} F_{m+s+2}
$$

Each row of the determinant is regarded as a pair of numbers, the subscript $s$ refers to the number of terms in the Fibonacci sequence skipped between successive pairs, and the subscript $m$ refers to the number of terms skipped between the two numbers of a pair.

It is simple exercise to establish the validity of (1), (2), and (3) using $\mathrm{F}_{\mathrm{m}+\mathrm{n}}=\mathrm{F}_{\mathrm{n}-1} \mathrm{~F}_{\mathrm{m}}+\mathrm{F}_{\mathrm{n}} \mathrm{F}_{\mathrm{m}+1}$. However, close inspection will show that (1), (2), and (3) are only special cases and/or variations of

$$
\begin{equation*}
\mathrm{F}_{\mathrm{p}} \mathrm{~F}_{\mathrm{q}}-\mathrm{F}_{\mathrm{p}-\mathrm{k}} \mathrm{~F}_{\mathrm{q}+\mathrm{k}}=(-1)^{\mathrm{p}-\mathrm{k}} \mathrm{~F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{q}+\mathrm{k}-\mathrm{p}} \tag{4}
\end{equation*}
$$

where $k=m+1$ and $q-p=s+1$.
This comparison is made easier when (4) is written as

$$
\left|\begin{array}{cc}
\mathrm{F}_{\mathrm{p}-\mathrm{k}} & \mathrm{~F}_{\mathrm{p}} \\
\mathrm{~F}_{\mathrm{q}} & \mathrm{~F}_{\mathrm{q}+\mathrm{k}}
\end{array}\right|=(-1)^{\mathrm{p}-\mathrm{k}+1} \mathrm{~F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{q}+\mathrm{k}-\mathrm{p}}
$$

thus suggesting a form for a related $3 \times 3$ matrix

$$
P=\left[\begin{array}{ccc}
F_{j-k} & F_{j} & F_{j+k} \\
F_{m-k} & F_{m} & F_{m+k} \\
F_{n-k} & F_{n} & F_{n+k}
\end{array}\right]
$$

A singular property of the $\operatorname{Det}(\mathrm{P})$ presents itself.
Theorem: $\operatorname{Det}(P)=0, k, j, m, n$ are integers.
Proof: There is no loss in generality to assume $\mathrm{j}>\mathrm{m}>\mathrm{n}$ and it is simply convenient to assume $k \geq 0$. By applying (4) it is apparent that the columns of $P$ are linearly dependent. We note by inspection that $F_{k}$ (column 3) $-F_{2 k}$ (column 2) $=(-1)^{\mathrm{k}+1} \mathrm{~F}_{\mathrm{k}}$ (column 1). Thus, the determinant is clearly zero (0).
Q. E. D.

Since the $\operatorname{Det}(P)=0$, a previous article of this Quarterly [3] suggests it would be interesting to consider the $\operatorname{Det}(P+a)$ where $P+a$ means a matrix $P$ with a added to each element of $P$. The generality of $j, m, n$, and $k$ would almost prohibit the techniques used by Whitney [3]. Hence procedures discussed by Bicknell in [1] and by Bicknell and Hoggatt in a previous article of this Quarterly [2] are employed. Using the formula [2]

$$
\operatorname{Det}(P+a)=\operatorname{Det}(P)+a \lambda(P)
$$

where $\lambda(P)$ is the change in the value of the determinant of $P$, when the number 1 is added to each element of $P$, we have

$$
\operatorname{Det}(P+a)=a \lambda(P),
$$

since $\operatorname{Det}(P)=0$. Now $\lambda(P)$ and the corresponding $\operatorname{Det}(P+a)$ are interesting in any one of the following forms. They are also derived with the aid of (4').
(a)

$$
\lambda(P)=\left|\begin{array}{ccc}
1 & 1 & 1 \\
F_{m-k}-F_{j-k} & F_{m}-F_{j} & F_{m+k}-F_{j+k} \\
F_{n-k}-F_{j-k} & F_{n}-F_{j} & F_{n+k}-F_{j+k}
\end{array}\right|
$$

or
(b) $\quad \lambda(P)=\left[F_{2 k}-F_{k}-(-1) k F_{k}\right]\left[(-1)^{m-k_{2}} F_{n-m}+(-1)^{j-k_{F}}{ }_{n-j}-(-1)^{j-k_{F}}{ }_{m-j}\right]$

Therefore,
(c) $\quad \operatorname{Det}(P+a)=\left|\begin{array}{ccc}a & a & a \\ F_{m-k}-F_{j-k} & F_{m}-F_{j} & F_{m+k}-F_{j+k} \\ F_{n-k}-F_{j-k} & F_{n}-F_{j} & F_{n+k}-F_{j+k}\end{array}\right|$
or

The first factors of (b) and (d) have a straightforward simplification if it is known in advance whether or not $k$ is even or odd. The various forms of $\lambda(\mathrm{P})$ and $\operatorname{Det}(\mathrm{P}+\mathrm{a})$ become much more intriguing once the interesting patterns in the subscripts and exponents and their relationship to $P$ are observed. These patterns could easily serve as mnemonic devices.

# EXPLORING SPECIAL FIBONACCI RELATIONS 

Brother U. Alfred, St. Mary's College, Calif.

In a previous exploration section, readers were introduced to the problem of generalized Fibonacci-Lucas relations. We denoted the terms of the generalized Fibonacci sequence as $f_{n}$ and those of the associated generalized Lucas sequence as $g_{n}$ where

$$
g_{n}=f_{n-1}+f_{n+1}
$$

Recall also that the sequence $(2,9)$ means the Fibonacci sequence with $f_{1}=2$ and $f_{2}=9$. The following represent some curious results obtained in trying to express $f_{n} g_{n}$ as a linear combination of $f^{\prime} s$ and $g^{\prime} s$.

| Sequence | Formula for $f_{n g n}$ |
| :--- | :--- |
| $(2,9)$ | $f_{n} g_{n}=f_{2 n+5}-g_{2 n-2}$ |
| $(3,7)$ | $f_{n} g_{n}=g_{2 n+3}-f_{2 n-1}$ |
| $(3,10)$ | $f_{n} g_{n}=g_{2 n+3}+f_{2 n}+g_{2 n-1}$ |
| $(3,11)$ | $f_{n} g_{n}=g_{2 n+4}-g_{2 n}-f_{2 n-3}$ |
| $(4,13)$ | $f_{n} g_{n}=g_{2 n+4}+f_{2 n-4}$ |
| $(5,11)$ | $f_{n} g_{n}=g_{2 n+3}+f_{2 n+3}+f_{2 n-2}$ |
| $(5,13)$ | $f_{n} g_{n}=g_{2 n+4}+f_{2 n-1}+f_{2 n-4}$ |
| $(6,13)$ | $f_{n} g_{n}=g_{2 n+4}+g_{2 n-1}$ |
| $(6,17)$ | $f_{n} g_{n}=g_{2 n+5}-f_{2 n+3}+f_{2 n-4}$ |
| $(7,17)$ | $f_{n} g_{n}=g_{2 n+4}+g_{2 n+2}+f_{2 n-4}$ |

Now, of course, it must be recognized that these linear expressions could be represented in an infinity of different ways. However, it does not seem that they are all one and the same relation. If not, then we have specific relations that characterize the individual sequences. So the following questions are raised:
(1) Can the above formulas for $f_{n g n}$ be unified into one formula?
(2) If not, can other instances be found of this type of phenomenon?
(3) When is it that we have particular formulas for each Fibonacci sequence rather than a general formula for all sequences?

All subscription correspondence should be addressed to Brother U. Alfred, St. Mary's College, Calif. All checks ( $\$ 4.00$ per year) should be made out to the Fibonacci Association or the Fibonacci Quarterly. Manuscripts intended for publication in the Quarterly should be sent to Verner E. Hoggatt, Jr., Mathematics Department, San Jose State College, San Jose, Calif. All manuscripts should be typed, double-spaced. Drawings should be made the same size as they will appear in the Quarterly, and should be done in India ink on either vellum or bond paper. Authors should keep a copy of the manuscripts sent to the editors.

## NOTICE TO ALL SUBSCRIBERS! ! !

Please notify the Managing Editor AT ONCE of any address change. The Post Office Department, rather than forwarding magazines mailed third class, sends them directly to the dead-letter office. Unless the addressee specifically requests the Fibonacci Quarterly to be forwarded at first class rates to the new address, he will not receive it. (This will usually cost about 30 cents for firstclass postage.) If possible, please notify us AT LEAST THREE WEEKS PRIOR to publication dates: February 15, April 15, October 15, and December 15.

The Fibonacci Association invites Educational Institutions to apply for Academic Membership in the Association. The minimum subscription fee is $\$ 25$ annually. (Academic Members will receive two copies of each issue and will have their names listed in the Journal.

# ALGEBRA THROUGH PROBLEM SOLVING BOOK REVIEW 

Brother U．Alfred，St．Mary＇s College，Calif．

A paperback entitled Algebra Through Problem Solving，written by Abraham P。Hillman，University of New Mexico，and Gerald L．Alexanderson，Univer－ sity of Santa Clara（1966，Allyn and Bacon）has appeared as one of a series entitled Topics in Contemporary Mathematics．The following sequence of topics is covered．

1．The Pascal Triangle
2．The Fibonacci and Lucas Numbers
3．Factorials
4．Arithmetic and Geometric Progressions
5．Mathematical Induction
6．The Binomial Theorem
7．Combinations and Permutations
8．Polynomial Equations
9．Determinants
10．Inequalities．
The manner of treatment is to give a presentation of the basic ideas in a succinct and cogent fashion and then allow the student to become familiar with these ideas by solving numerous andvaried problems．This approach，it seems to the present reviewer，is highly commendable．

Of particular interest is the role given the Fibonacci and Lucas numbers． Note that these sequences are introduced early in the book。 In Chapter 2，they are used in the main to provide the student with an opportunity to make mathe－ matical conjectures on new and unfamiliar material．But the authors do not stop there．As might be expected，they play a key role in the chapter on math－ ematical induction and are brought in occasionally in other portions of the book as well．

An unofficial and rapid count of these loci apart from Chapter 2 is given below．

In the chapter on mathematical induction，p．35，No．4；p．37，No．17， p．38，Nos．19－25 inclusive；in the chapter on the binomial theorem，Nos．33－ 36 ，pp．49－50；in the chapter on determinants，No。17，pp．94－95；in the chapter on inequalities，No．5，p．107，No．28，p． 117.

# OPTIMALITY PROOF FOR THE SYMMETRIC FIBONACCI SEARCH TECHNIQUE 

Mordecai Avriel and Douglass J. Wilde, Stanford University, Stanford, Calif.

An important problem in engineering, economics, and statistics is to find the maximum of a function. When the function has only one stationary point, the maximum, and when it depends on a single variable in a finite interval, the most efficient way to find the maximum is based on the Fibonacci numbers. The procedure, now known widely as "Fibonacci search," was discovered and shown optimal in a minimax sense by Kiefer [1]. S. Johnson [2] gave a different demonstration. Oliver and Wilde $[3,4]$ extended the procedure to the case where, in order to distinguish between adjacent measurements, a non-negligible distance must be preserved between them. Although this modification, called the symmetric Fibonacci technique is described informally in [4], where numerous extensions are also discussed the present paper gives the firstcomplete, precise description, and formal optimality proof.

Let $y(x)$ be a unimodal function, i. e., one with a unique relative maximum value obtained at $x=x^{*}$ on the closed interval $[a, b]$; thus

$$
\begin{equation*}
y\left(x^{*}\right)=\max _{a \leq x \leq b} y(x) \tag{1}
\end{equation*}
$$

and $\mathrm{a} \leq \mathrm{x}_{1}<\mathrm{x}_{2} \leq \mathrm{x}^{*}$ implies $\mathrm{y}\left(\mathrm{x}_{1}\right)<\mathrm{y}\left(\mathrm{x}_{2}\right) ; \mathrm{x}^{*} \leq \mathrm{x}_{1}<\mathrm{x}_{2} \leq \mathrm{b}$ implies $\mathrm{y}\left(\mathrm{x}_{1}\right)$ $>y\left(x_{2}\right)$. As a practical consideration, assume that $y(x)$ canbe measured only with finite accuracy, but there is a $\delta>0$ such that if $\left|\mathrm{x}_{1}-\mathrm{x}_{2}\right| \geq \delta$ the measurements of $y\left(x_{1}\right)$ and $y\left(x_{2}\right)$ will be equal only if $x_{1}$ and $x_{2}$ lie on opposite sides of $x^{*}$.

A search strategy $S(n, \delta)$ on $[a, b]$ is a plan for evaluating the function at $n$ distinct points $x_{1}, x_{2}, \cdots, x_{n}$, where the location of $x_{k+1}$ depends on $\mathrm{y}\left(\mathrm{x}_{\mathrm{j}}\right)$ for $\mathrm{j} \leq \mathrm{k}$ and where

$$
\begin{equation*}
\left|x_{j}-x_{k}\right| \geq \delta \quad j \neq k, \quad 1 \leq j, \quad k \leq n \tag{2}
\end{equation*}
$$

The plan terminates after successive reduction of a starting interval on which the function is defined to a final interval of a required length, containing $\mathrm{x}^{*}$.

Suppose $k$ function evaluations have been performed, and let $m_{k}$ be such that

$$
\begin{equation*}
\mathrm{y}\left(\mathrm{~m}_{\mathrm{k}}\right)=\max \left\{\mathrm{y}\left(\mathrm{x}_{1}\right), \cdots, \mathrm{y}\left(\mathrm{x}_{\mathrm{k}}\right)\right\} \tag{3}
\end{equation*}
$$

Let

$$
\begin{align*}
& L_{k}=\left\{x_{j}: x_{j}<m_{k}, j \leq k\right\} \cup\{a\}  \tag{4}\\
& R_{k}=\left\{x_{j}: x_{j}>m_{k}, j \leq k\right\} \cup\{b\} \tag{5}
\end{align*}
$$

and

$$
\begin{align*}
& \ell_{\mathrm{k}}=\operatorname{Sup} \mathrm{L}_{\mathrm{k}}  \tag{6}\\
& \mathrm{r}_{\mathrm{k}}=\operatorname{Inf} \mathrm{R}_{\mathrm{k}}
\end{align*}
$$

Since $y$ is unimodal, it is clear that $x^{*}$ must be in the interval $\left[\ell_{k}, r_{k}\right]$.
The purpose of this paper is to derive a search strategy $S_{o p}(n, \delta)$ that is optimal in the sense that it maximizes the length of the starting interval for whatever final interval is given. From (2) - (7) it follows that the final interval for any $n>1$ is

$$
\begin{equation*}
r_{n}-\ell_{n} \geq 2 \delta \tag{8}
\end{equation*}
$$

By choosing the required length ( $\geq 2 \delta$ ) of the final interval we rescale the system as follows:

$$
\begin{equation*}
\bar{r}_{\mathrm{n}}-\bar{\ell}_{\mathrm{n}}=\lambda\left(\mathrm{r}_{\mathrm{n}}-\ell_{\mathrm{n}}\right)=1, \quad \lambda>0 \tag{9}
\end{equation*}
$$

$$
\begin{equation*}
\bar{\delta}=\lambda \delta \tag{10}
\end{equation*}
$$

$$
\begin{equation*}
\bar{x}=\lambda(x-a) \tag{11}
\end{equation*}
$$

Thus the new strategy $\overline{\mathrm{S}}(\mathrm{n}, \bar{\delta})$ is defined on $\left[0, \overline{\mathrm{D}}_{\mathrm{n}}\right]$, where $\overline{\mathrm{D}}_{\mathrm{n}}=\lambda(\mathrm{b}-\mathrm{a})$, and it yields a final interval of unit length.

The symmetric Fibonacci search is a search strategy for a starting interval $\left[0, \overline{\mathrm{D}}_{\mathrm{n}}^{\mathrm{F}}\right]$ where the right end point $\overline{\mathrm{D}}_{\mathrm{n}}^{\mathrm{F}}$ is given by

$$
\begin{equation*}
\overline{\mathrm{D}}_{\mathrm{n}}^{\mathrm{F}}=\mathrm{F}_{\mathrm{n}+1}-\mathrm{F}_{\mathrm{n}-1} \delta, \quad \mathrm{n}=1,2, \cdots \tag{12}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{F}_{\mathrm{n}+2}=\mathrm{F}_{\mathrm{n}+1}+\mathrm{F}_{\mathrm{n}} \quad\left(\mathrm{~F}_{0}=0, \quad \mathrm{~F}_{1}=1\right) \tag{13}
\end{equation*}
$$

are the Fibonacci numbers. The strategy is defined by the rules

$$
\begin{equation*}
\overline{\mathrm{x}}_{\mathrm{i}}^{\mathrm{F}}=\mathrm{F}_{\mathrm{n}}-\mathrm{F}_{\mathrm{n}-2} \bar{\delta} \tag{14}
\end{equation*}
$$

and

$$
\begin{equation*}
\overline{\mathrm{x}}_{\mathrm{k}+1}^{\mathrm{F}}=\bar{\ell}_{\mathrm{k}}+\overline{\mathrm{r}}_{\mathrm{k}}-\overline{\mathrm{m}}_{\mathrm{k}} \tag{15}
\end{equation*}
$$

Lemma: The symmetric Fibonacci search defined above is an $\overline{\mathrm{S}}(\mathrm{n}, \bar{\delta})$ search strategy for $\left[0, \overline{\mathrm{D}}_{\mathrm{n}}^{\mathrm{F}}\right]$ with $\overline{\mathrm{r}}_{\mathrm{n}}-\bar{\ell}_{\mathrm{n}}=1$.

Proof: By induction on $n$. The lemma is trivially true for $n=1$, since by (3) - (7) $\bar{l}_{1}=0$ and $\bar{r}_{1}=1$. For $n=2, \quad \bar{D}_{2}^{\mathrm{F}}=2-\bar{\delta}$ and $\overline{\mathrm{x}}_{1}^{\mathrm{F}}=1$, implying that $\bar{\ell}_{1}=0, \bar{r}_{1}=2-\bar{\delta}$ and consequently $\bar{x}_{2}=1-\bar{\delta}$ by (15). Thus $\left|\overline{\mathrm{x}}_{1}^{\mathrm{F}}-\overline{\mathrm{x}}_{2}^{\mathrm{F}}\right|=\bar{\delta}$ and for any unimodal function either $\overline{\mathrm{m}}_{2}=\overline{\mathrm{x}}_{1}^{\mathrm{F}}$ or $\overline{\mathrm{m}}_{2}=\overline{\mathrm{x}}_{2}^{\mathrm{F}}$, and in both cases $\bar{r}_{2}-\bar{\ell}_{2}=1$ 。

Now assume the lemma true for $\mathrm{n}=\mathrm{N} \ell 2$ ). Then $\overline{\mathrm{D}}_{\mathrm{N}+1}^{\mathrm{F}}=\mathrm{F}_{\mathrm{N}+2}-\mathrm{F}_{\mathrm{N}} \bar{\delta}^{\bar{\delta}}$ and $\overline{\mathrm{X}}_{1}^{\mathrm{F}}=\mathrm{F}_{\mathrm{N}+1}-\mathrm{F}_{\mathrm{N}-1} \bar{\delta}=\overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}}$. Consequently, $\bar{\ell}_{1}=0, \overline{\mathrm{r}}_{1}=\mathrm{F}_{\mathrm{N}+2}-\mathrm{F}_{\mathrm{N}} \bar{\delta}$ and $\overline{\mathrm{x}}_{2}^{\mathrm{F}}=\mathrm{F}_{\mathrm{N}}-\mathrm{F}_{\mathrm{N}-2} \bar{\delta}=\overline{\mathrm{D}}_{\mathrm{N}-1}^{\mathrm{F}}$. Also $\left|\overline{\mathrm{x}}_{1}^{\mathrm{F}}-\overline{\mathrm{x}}_{2}^{\mathrm{F}}\right|=\overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}}-\overline{\mathrm{D}}_{\mathrm{N}-1}^{\mathrm{F}} \geq 1-\bar{\delta} \geq \bar{\delta}$ 。 If $\overline{\mathrm{m}}_{2}$ $=\overline{\mathrm{x}}_{2}^{\mathrm{F}}$ then $\bar{\ell}_{2}=0$ and $\overline{\mathrm{r}}_{2}=\overline{\mathrm{x}}_{1}^{\mathrm{F}}=\overline{\mathrm{D}}_{\mathrm{N}} \mathrm{F}$. Thus $0 \leq \overline{\mathrm{x}}^{*} \leq \overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}}$ with one evaluation of the function at $\overline{\mathrm{D}}_{\mathrm{N}-1}^{\mathrm{F}}$ and $\mathrm{G}_{\mathrm{y}}$ the induction hypothesis the lemma is true for this case. If $\overline{\mathrm{m}}_{2}=\overline{\mathrm{X}}_{1} \mathrm{~F}_{\text {, then }} \bar{\ell}_{2}=\overline{\mathrm{x}}_{2}^{\mathrm{F}}=\overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}} \mathrm{F}$ and $\overline{\mathrm{r}}_{2}=\overline{\mathrm{D}}_{\mathrm{N}+1}^{\mathrm{F}}$. Define the new variable $\hat{\mathrm{x}}^{\mathrm{F}}=\overline{\mathrm{D}}_{\mathrm{N}+1}^{\mathrm{F}}-\overline{\mathrm{x}} \mathrm{F}$ so that $0 \leq \hat{\mathrm{x}}^{\mathrm{F}} \leq \overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{N}}$ with one function evaluation at $\bar{D}_{\mathrm{N}-1}^{\mathrm{F}}$. Thus by induction the lemma is true for this case, too.

Note that if $y\left(\bar{x}_{\mathrm{K}+1}^{\mathrm{F}}\right)=\mathrm{y}\left(\overline{\mathrm{m}}_{\mathrm{k}}\right)$ and say $\overline{\mathrm{m}}_{\mathrm{k}}>\overline{\mathrm{x}}_{\mathrm{k}+1}^{\mathrm{F}}, \overline{\mathrm{x}}^{*}$ is known to lie in the interval $\left[\bar{x}_{\mathrm{k}+1}^{\mathrm{F}}, \overline{\mathrm{m}}_{\mathrm{k}}\right]$. As $\overline{\mathrm{m}}_{\mathrm{k}+1}=\overline{\mathrm{m}}_{\mathrm{k}}$ or $\overline{\mathrm{m}}_{\mathrm{k}+1}=\overline{\mathrm{x}}_{\mathrm{k}+1}^{\mathrm{F}}$, the Fibonacci
search plan suggests reducing the interval $\left[\bar{\ell}_{k}, \bar{r}_{k}\right]$ to either $\left[\bar{\ell}_{k}, \bar{m}_{k}\right.$ ］or ［ $\overline{\mathrm{x}}_{\mathrm{k}+1}, \overline{\mathrm{r}}_{\mathrm{k}}$ ］．An improved choice could be made in this case by taking the next interval as $\left[\bar{\ell}_{\mathrm{k}+1}, \overline{\mathrm{r}}_{\mathrm{k}+1}\right]=\left[\overline{\mathrm{x}}_{\mathrm{k}+1}^{\mathrm{F}}, \overline{\mathrm{m}}_{\mathrm{k}}\right]$ which can be the starting interval for a new $\overline{\mathrm{S}}(\mathrm{n}-\mathrm{k}-2, \bar{\delta})$ Fibonacci plan．This fortuitous situation is deliberately excluded from the theorem following in order to simplify the proof．

Theorem：The symmetric Fibonacci search plan is the unique $\overline{\mathrm{S}}_{\mathrm{op}}(\mathrm{n}, \bar{\delta})$ strategy among all $\overline{\mathrm{S}}(\mathrm{n}, \bar{\delta})$ strategies，provided $\mathrm{y}\left(\overline{\mathrm{x}}_{\mathrm{k}+1}\right) \neq \mathrm{y}\left(\mathrm{m}_{\mathrm{k}}\right)$ for every $\mathrm{k}=1,2, \cdots, \mathrm{n}-1$ 。
Proof：by induction on $n$ ．For $n=1$ the proof is obvious because all $\bar{D}_{1}=$ $\overline{\mathrm{D}}_{1}^{\mathrm{F}}=1$ ．For $\mathrm{n}=2$ we can assume without loss of generality that $\overline{\mathrm{x}}_{1}>\overline{\mathrm{x}}_{2}$ 。 Then any $\overline{\mathrm{S}}(\mathrm{n}, \bar{\delta})$ must satisfy $\overline{\mathrm{x}}_{1}=1, \overline{\mathrm{D}}_{2}-\overline{\mathrm{x}}_{1} \leq 1-\bar{\delta}$ ，yielding $\overline{\mathrm{D}}_{2} \leq 2-\bar{\delta}=$ $\overline{\mathrm{D}}_{2}^{\mathrm{F}}$ 。 Assume now that the theorem is true for $\mathrm{n}=\mathrm{N} \geq 2$ ，then for an $\overline{\mathrm{S}}(\mathrm{N}+$ $1, \bar{\delta})$ strategy let $\overline{\mathrm{x}}_{1}>\overline{\mathrm{x}}_{2}$ and $\overline{\mathrm{m}}_{2}=\overline{\mathrm{x}}_{2}$ ．Hence $\bar{\ell}_{2}=0, \overline{\mathrm{r}}_{2}=\overline{\mathrm{x}}_{1}$ ，and we have an $\overline{\mathrm{S}}(\mathrm{N}, \bar{\delta})$ strategy on $\left[0, \overline{\mathrm{x}}_{1}\right]$ ．By induction

$$
\begin{equation*}
\overline{\mathrm{x}}_{1} \leq \overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}} \tag{16}
\end{equation*}
$$

If $\bar{m}_{2}=\overline{\mathrm{x}}_{1}$ ，then $\bar{\ell}_{2}=\overline{\mathrm{x}}_{2}, \overline{\mathrm{r}}_{2}=\overline{\mathrm{D}}_{\mathrm{N}+1}$ ，and by induction therefore

$$
\begin{equation*}
\overline{\mathrm{D}}_{\mathrm{N}+1}-\overline{\mathrm{x}}_{2} \leq \overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}} \tag{17}
\end{equation*}
$$

However，

$$
\begin{equation*}
\overline{\mathrm{x}}_{2} \leq \overline{\mathrm{D}}_{\mathrm{N}-1}^{\mathrm{F}} \tag{18}
\end{equation*}
$$

also by induction，since if $\overline{\mathrm{X}}^{*}<\overline{\mathrm{x}}_{2}$ then $\overline{\mathrm{x}}^{*}$ has to be located by an $\overline{\mathrm{S}}(\mathrm{N}-1, \bar{\delta})$ strategy on $\left[0, \bar{x}_{2}\right]$ ．Thus addition of（17）and（18）yields

$$
\begin{equation*}
\overline{\mathrm{D}}_{\mathrm{N}+1} \leq \overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}}+\overline{\mathrm{D}}_{\mathrm{N}-1}^{\mathrm{F}} \tag{19}
\end{equation*}
$$

But $\overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}}+\overline{\mathrm{D}}_{\mathrm{N}-1}^{\mathrm{F}}=\overline{\mathrm{D}}_{\mathrm{N}+1}^{\mathrm{F}}$ by（12），and this shows that the symmetric Fibonacci search is indeed optimal．

Moreover，we observe that

$$
\begin{equation*}
\overline{\mathrm{D}}_{\mathrm{N}+1}-\overline{\mathrm{x}}_{1} \leq \overline{\mathrm{D}}_{\mathrm{N}-1}^{\mathrm{F}} \tag{20}
\end{equation*}
$$

by an argument similar to that used in (18). Relations (16) - (20) show that the symmetric Fibonacci search is the only way to achieve the maximum value $\overline{\mathrm{D}}_{\mathrm{N}}=\overline{\mathrm{D}}_{\mathrm{N}}^{\mathrm{F}}$ 。

## AN EXPRESSION FOR GENERALIZED FIBONACCI NUMBERS

David E. Ferguson, Programmatics Incorporated, Los Angeles, Calif.

An interesting expression for the Fibonacci numbers is presented here which relies on the modulo three value of the subscript.

$$
\begin{equation*}
F_{3 a}=1-\sum_{i=0}^{a-1}\binom{2 i+a-1}{3 i}(-1)^{a-i} 8^{i} \quad(a>0) \tag{1a}
\end{equation*}
$$

$$
\begin{array}{ll}
\text { (1b) } \quad F_{3 a+1}=1-2 \sum_{i=0}^{a-1}\binom{2 i+a}{3 i+1}(-1)^{a-i} 8^{i} & (a \geq 0)  \tag{1b}\\
\text { (1c) } \quad F_{3 a+2}=1-4 \sum_{i=0}^{a-1}\binom{2 i+a+1}{3 i+2}(-1)^{a-i} 8^{i} & (a \geq 0)
\end{array}
$$

This is a special case of a more general expression for the generalized Fibonacci numbers [1].

$$
\begin{align*}
& \mathrm{V}_{\mathrm{n}, \mathrm{~m}}=1 \quad(\mathrm{~m}=-\mathrm{n}+1, \cdots, 0)  \tag{2a}\\
& \mathrm{V}_{\mathrm{n}, \mathrm{~m}}=\sum_{\mathrm{k}=1}^{\mathrm{n}} \mathrm{~V}_{\mathrm{n}, \mathrm{~m}-\mathrm{k}}
\end{align*}
$$

It is seen that $\mathrm{F}_{\mathrm{m}}=\mathrm{V}_{2, \mathrm{~m}-2}$.
It is interesting to note that these numbers arise in the analysis of polyphase merge-sorting with $n+1$ tapes. The $V_{n, m}$ represent the total number of strings on all the tapes and also the length of strings (assuming initial length of 1) at each step of the polyphase merge process. A description of the polyphase merge-sort can be found in [2].

The general expression can be written as:

$$
\begin{gather*}
\mathrm{V}_{\mathrm{n}, \mathrm{a}(\mathrm{n}+1)+\mathrm{b}}=1+2^{\mathrm{b}-1}(\mathrm{n}-1) \sum_{\mathrm{i}=0}^{a}\binom{\text { in }+a+b-1}{a-i}(-1)^{a-i}\left(2^{n+1}\right)^{i}  \tag{3}\\
(\mathrm{~b}=1, \cdots, n+1), \quad(a \geq 0) .
\end{gather*}
$$

[Oct. 1966]
Let

$$
f_{n}(x)=\sum_{m=0}^{\infty} v_{n, m} x^{m}
$$

It follows immediately that
$\left(1-x-x^{2}-\cdots-x^{n}\right) f_{n}(x)=1+(n-1) x+(n-2) x^{2}+\cdots+x^{n-1}$.
Therefore

$$
\begin{align*}
f_{n}(x) & =\frac{1+(n-1) x+(n-2) x^{2}+\cdots+x^{n-1}}{1-x-x^{2}-\cdots-x^{n}} \\
& =\frac{1+(n-2) x-x^{2}-\cdots-x^{n}}{1-2 x+x^{n+1}}  \tag{4}\\
& =\frac{1}{1-x}+\frac{(n-1) x}{1-2 x+x^{n+1}}
\end{align*}
$$

If

$$
\frac{1}{1-2 x+x^{n+1}}=\sum_{m=0}^{\infty} W_{n, m^{2}} x^{m}
$$

the sequence $W_{n, m}$ is defined by:

$$
\begin{array}{ll}
\mathrm{W}_{\mathrm{n}, \mathrm{~m}}=0 & (\mathrm{~m}<0) \\
\mathrm{W}_{\mathrm{n}, \mathrm{~m}}=1 & (\mathrm{~m}=0) \tag{5b}
\end{array}
$$

$$
\begin{equation*}
\mathrm{W}_{\mathrm{n}, \mathrm{~m}}=2 \mathrm{~W}_{\mathrm{n}, \mathrm{~m}-1}-\mathrm{W}_{\mathrm{n}, \mathrm{~m}-\mathrm{n}-1} \quad(\mathrm{~m}>0) \tag{5c}
\end{equation*}
$$

From Eq. (4) $\quad V_{n, m}=1+(n-1) W_{n, m-1} \quad(m>0)$
Theorem:

$$
\begin{equation*}
W_{n, a(n+1)+b}=\sum_{j=0}^{\infty}\binom{a+b+n j}{(n+1) j+b} 2^{b+(n+1) j}(-1)^{a-j} \tag{6}
\end{equation*}
$$

(This formula immediately yields the identity (3).)
Proof:

$$
\begin{aligned}
\frac{1}{1-2 x+x^{n+1}} & =\sum_{m=0}^{\infty}\left(2 x-x^{n+1}\right)^{m} \\
& =\sum_{m=0}^{\infty} \sum_{k=0}^{\infty}\binom{m}{k} 2^{k}(-1)^{m-k_{x}(n+1) m-n k}
\end{aligned}
$$

Rearranging this sum in terms of powers of $x$, let $(n+1) a+b=(n+1) m-$ nk. It follows that $k=b(\bmod (n+1))$, so $k=(n+1) j+b$ for some $j \geq 0$ 。 Changing the sum on $m$ and $k$ into a sum on $a, b$ and $j$, and noting that $m=a+b+n j$, results in:

$$
\sum_{a=0}^{\infty} \sum_{b=0}^{\infty} x^{(n+1) a+b} \sum_{j=0}^{\infty}\binom{a+b+n j}{(n+1) j+b} 2^{(n+1) j+b}(-1)^{a-j}
$$

This completes the proof. A similar method was used by Polya [3] to solve another recurrence relation.

Another interesting expression which arises from this analysis is the general expression for the numbers defined by:
(7a)
(7b)

$$
\begin{array}{lr}
\mathrm{U}_{\mathrm{n}, \mathrm{~m}}=0 & (\mathrm{~m}=-\mathrm{n}+1, \cdots,-1) \\
\mathrm{U}_{\mathrm{n}, \mathrm{~m}}=1 & (\mathrm{~m}=0) \\
\mathrm{U}_{\mathrm{n}, \mathrm{~m}}=\sum_{i=1}^{m} \mathrm{U}_{\mathrm{n}, \mathrm{~m}-\mathrm{i}} & (\mathrm{~m}>0)
\end{array}
$$

It is seen that $F_{m}=U_{2, m-1}$.
These numbers also arise in the analysis of polyphase merge-sorting; they represent the number of strings produced at each step of the process.

The general expression is:

$$
\begin{gathered}
U_{n, a(n+1)+b}=2^{b-1} \sum_{i=0}^{a}\left\{\binom{i n+a+b}{a-i}+\binom{i n+a+b-1}{a-i-1}\right\}(-1)^{a-m}\left(2^{n+1}\right)^{n} \\
(b=0, \cdots, n), \quad(a+b>0)
\end{gathered}
$$

The proof is similar to the above and is omitted.

## ACKNOWLEDGEMENT

The author is indebted to Donald E. Knuth for suggesting the proof used above.

FIBONACCI YET AGAIN
J. A. H. Hunter

Consider a triangle such that the square of one side equals the product of the other two sides.

Then we have sides: $X, \sqrt{X Y}$, and $Y$; say $X>Y$.
Eliminating an common factor we may set $X=a^{2}, Y=b^{2}$, so that the "reduced" sides become $a^{2}$, $a b, b^{2}$.

Then, for a triangle, we must have $a b+b^{2}>a^{2}$ which requires $\sqrt{5}-$ 1) $/ 2<\mathrm{b} / \mathrm{a}<(\sqrt{5}+1) / 2$ 。

Hence a sufficient condition for a triangle that meets the requirements is

$$
\mathrm{F}_{2 \mathrm{n}-1} / \mathrm{F}_{2 \mathrm{n}}<\mathrm{b} / \mathrm{a}<\mathrm{F}_{2 \mathrm{n}} / \mathrm{F}_{2 \mathrm{n}-1} \quad \text { with } \quad \mathrm{X}=\mathrm{ka}^{2}, \mathrm{Y}=\mathrm{kb}^{2}
$$

Drawings should be made the same size as they will appear in the Quarterly, and should be done in India ink on either vellum or bond paper. Authors should keep a copy of the manuscripts sent to the editors.

# A POWER IDENTITY FOR SECOND-ORDER RECURRENT SEQUENCES 

V.E. Hoggatt, Jro, San Jose State College, San Jose, Calif. and D.A. Lind, University of Virginia, Charlottesville, Va.

## 1. INTRODUCTION

The following hold for all integers $n$ and $k$ :

$$
\begin{aligned}
\mathrm{F}_{\mathrm{n}+\mathrm{k}}= & \mathrm{F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{n}+1}+\mathrm{F}_{\mathrm{k}-1} \mathrm{~F}_{\mathrm{n}}, \\
\mathrm{~F}_{\mathrm{n}+\mathrm{k}}^{2}= & \left(\mathrm{F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{k}-1}\right) \mathrm{F}_{\mathrm{n}+2}^{2}+\left(\mathrm{F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{k}-2}\right) \mathrm{F}_{\mathrm{n}+1}^{2}-\left(\mathrm{F}_{\mathrm{k}-1} \mathrm{~F}_{\mathrm{k}-2}\right) \mathrm{F}_{\mathrm{n}}^{2}, \\
\mathrm{~F}_{\mathrm{n}+\mathrm{k}}^{3}= & \left(\mathrm{F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{k}-1} \mathrm{~F}_{\mathrm{k}-2} / 2\right) \mathrm{F}_{\mathrm{n}+3}^{3}+\left(\mathrm{F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{k}-1} \mathrm{~F}_{\mathrm{k}-3}\right) \mathrm{F}_{\mathrm{n}+2}^{3}-\left(\mathrm{F}_{\mathrm{k}} \mathrm{~F}_{\mathrm{k}-2} \mathrm{~F}_{\mathrm{k}-3}\right) \mathrm{F}_{\mathrm{n}+1}^{3} \\
& -\left(\mathrm{F}_{\mathrm{k}-1} \mathrm{~F}_{\mathrm{k}-2} \mathrm{~F}_{\mathrm{k}-3} / 2\right) \mathrm{F}_{\mathrm{n}}^{3}
\end{aligned}
$$

These identities suggest that there is a general expansion of the form

$$
\begin{equation*}
F_{n+k}^{p}=\sum_{j=0}^{p} a_{j}(k, p) F_{n+j}^{p} \tag{1.1}
\end{equation*}
$$

Here we show such an expansion does indeed exist, find an expression for the coefficients $a_{j}(k, p)$, and generalize (1.1) to second order recurrent sequences.

## 2. A FIBONACCI POWER IDENTITY

Define the Fibonomial coefficients $\left[\begin{array}{c}m \\ r\end{array}\right]$ by

$$
\left[\begin{array}{c}
m \\
r
\end{array}\right]=\frac{F_{m} F_{m-1} \cdots F_{m-r+1}}{F_{1} F_{2} \cdots F_{r}} \quad(r>0) ;\left[\begin{array}{c}
m \\
0
\end{array}\right]=1
$$

Jarden [4] proved that the term-by-term product $z_{n}$ of $p$ sequences each obeying the Fibonacci recurrence satisfies
[Oct. 1966]
A POWER IDENTITY FOR
SECOND-ORDER RECURRENT SEQUENCES

$$
\sum_{j=0}^{p+1}(-1)^{j(j+1) / 2}\left[\begin{array}{c}
p+1 \\
j
\end{array}\right]_{n-j}
$$

for integral $n$. In particular, $z_{n}=F_{n}^{p}$ obeys (2.1). Carlitz, [1, Section 1] has shown that the determinant

$$
\mathrm{D}_{\mathrm{p}}=\left|\mathrm{F}_{\mathrm{n}+\mathrm{r}+\mathrm{s}}^{\mathrm{p}}\right|(\mathrm{r}, \mathrm{~s}=0,1, \cdots, \mathrm{p})
$$

has the value

$$
D_{p}=(-1)^{p(p+1)(n+1) / 2} \prod_{j=0}^{p}\binom{p}{j} \cdot\left(F_{1}^{p} F_{2}^{p-1} \cdots F_{p}\right)^{2} \neq 0
$$

implying that the $p+1$ sequences $\left\{F_{n}^{p}\right\},\left\{F_{n+1}^{p}\right\}, \cdots,\left\{F_{n+p}^{p}\right\}$ are linearly independent over the reals. Since each of these sequences obeys the $(p+1)^{\text {th }}$ order recurrence relation (2.1), they must span the space of solutions of (2.1). Therefore an expansion of the form (1.1) exists.

To evaluate the coefficients $a_{j}(k, p)$ in (1.1) we first put $k=0,1, \cdots, p$, giving $\mathrm{a}_{\mathrm{j}}(\mathrm{k}, \mathrm{p})=\delta_{\mathrm{jk}}$ for $0 \leq \mathrm{j}, \mathrm{k} \leq \mathrm{p}$, where $\delta_{\mathrm{jk}}$ is the Kronecker delta defined by $\delta_{j k}=0$ if $j \neq k, \quad \delta_{k k}=1$. Next we show that the sequence

$$
\left\{\mathrm{a}_{\mathrm{j}}(\mathrm{k}, \mathrm{p})\right\}_{\mathrm{k}=0}^{\infty}
$$

obeys (2.1) for $j=0,1, \cdots, p$. Indeed from (1.1) we find

$$
\begin{aligned}
0 & =\sum_{r=0}^{p+1}(-1)^{r(r+1) / 2}\left[\begin{array}{c}
p+1 \\
r
\end{array}\right] F_{n+k-r}^{p} \\
& =\sum_{j=0}^{p}\left\{\sum_{r=0}^{p+1}(-1)^{r(r+1) / 2}\left[\begin{array}{c}
p+1 \\
r
\end{array}\right] a_{j}(k-r, p)\right\} F_{n+j}^{p} .
\end{aligned}
$$

But the $F_{n+j}^{p}(j=0,1, \cdots, p)$ are linearly independent, so that

$$
\sum_{r=0}^{p+1}(-1)^{r(r+1) / 2}\left[\begin{array}{c}
p+1 \\
r
\end{array}\right] a_{j}(k-r, p)=0(j=0,1, \cdots, p)
$$

[Oct.
Now consider $b_{j}(k, p)=\left(F_{k} F_{k-1} \cdots F_{k-p}\right) / F_{k-j}\left(F_{j} F_{j-1} \cdots F_{i-1} F_{j-p}\right)$ for $j=0,1, \cdots, p-1, b_{p}(k, p)=\left[\begin{array}{l}k \\ p\end{array}\right]$, together with the convention that $F_{0} / F_{0}=1$. Clearly $b_{j}(k, p)=\delta_{j k}$ for $0 \leq j, k \leq p$. Since $\left\{b_{j}(k, p)\right\}_{k=0}^{\infty}$ is the term-byterm product of $p$ Fibonacci sequences, it must obey (2.1). Thus $\left\{\mathrm{a}_{\mathrm{j}}(\mathrm{k}, \mathrm{p})\right\}_{\mathrm{k}=0}^{\infty}$ and $\left\{b_{j}(k, p)\right\}_{k=0}^{\infty}$ obey the same $(p+1)^{\text {th }}$ order recurrence relation and have their first $p+1$ values equal $(j=0,1, \cdots, p)$, so that $a_{j}(k, p)=b_{j}(k, p)$. Since $F_{-n}=(-1)^{n+1} F_{n}$, it follows that

$$
F_{-1} \cdots F_{j-p}=F_{p-j} \cdots F_{1}(-1)^{(p-j)(p-j+3) / 2}
$$

so that for $j=0,1, \cdots, p-1$, we have

$$
\begin{aligned}
a_{j}(k, p) & =(-1)^{(p-j)(p-j+3) / 2}\left(\frac{F_{k} F_{k-1} \cdots F_{k-p+1}}{F_{p} F_{p-1} \cdots F_{1}}\right)\left(\frac{F_{p} F_{p-1} \cdots F_{1}}{\left(F_{j} \cdots F_{1}\right)\left(F_{p-j} \cdots F_{1}\right)}\right)\left(\frac{F_{k-p}}{F_{k-j}}\right) \\
& =(-1)^{(p-j)(p-j+3) / 2}\left[\begin{array}{l}
k \\
p
\end{array}\right]\left[\begin{array}{l}
p \\
j
\end{array}\right]\left(F_{k-p} / F_{k-j}\right),
\end{aligned}
$$

which is also valid for $j=p$ using the convention $F_{0} / F_{0}=1$. Then (1.1) becomes

$$
F_{n+k}^{p}=\sum_{j=0}^{p}(-1)^{(p-j)(p-j+3) / 2}\left[\begin{array}{l}
k  \tag{2.2}\\
p
\end{array}\right]\left[\begin{array}{l}
p \\
j
\end{array}\right]\left(F_{k-p} / F_{k-j}\right) F_{n+j}^{p}
$$

for all $k$. We remark that since consecutive $p^{\text {th }}$ powers of the natural numbers obey

$$
\sum_{j=0}^{p+1}(-1)^{p-j}\binom{p+1}{j}(n+j)^{p}=0
$$

a development similar to the above leads to

$$
\begin{equation*}
(\mathrm{n}+\mathrm{k})^{\mathrm{p}}=\sum_{j=0}^{\mathrm{p}}(-1)^{\mathrm{p}-\mathrm{j}}\binom{\mathrm{k}}{\mathrm{p}}\binom{\mathrm{p}}{\mathrm{j}}\binom{\mathrm{k}-\mathrm{p}}{\mathrm{k}-\mathrm{j}}(\mathrm{n}+\mathrm{j})^{\mathrm{p}} \tag{2.3}
\end{equation*}
$$

a result parallel to (2.2)

## 3. EXTENSION TO SECOND-ORDER RECURRENT SEQUENCES

We now generalize the result of Section 2. Consider the second-order linear recurrence relation

$$
\begin{equation*}
y_{n+2}=p y_{n+1}-q y_{n} \quad(q \neq 0) \tag{3.1}
\end{equation*}
$$

Let $a$ and $b$ be the roots of the auxiliary polynomial $x^{2}-p x+q$ of (3.1), Let $w_{n}$ be any sequence satisfying (3.1), and define $u_{n}$ by $u_{n}=\left(a^{n}-b^{n}\right) /$ $(a-b)$ if $a \neq b$, and $u_{n}=n a^{n-1}$ if $a=b$, so that $u_{n}$ also satisfies (3.1). Following [4], we define the u-generalized binomial coefficients $\left[\begin{array}{c}\mathrm{m} \\ \mathrm{r}\end{array}\right]_{\mathrm{u}}$ by

$$
\left[\begin{array}{c}
m \\
r
\end{array}\right]_{u}=\frac{u_{m} u_{m-1} \cdots u_{m-r+1}}{u_{1} u_{2} \cdots u_{r}} \quad(r>0) ;\left[\begin{array}{c}
m \\
0
\end{array}\right]_{u}=1 .
$$

Jarden [4] has shown that the product $x_{n}$ of $p$ sequences each obeying (3.1) satisfies the $(p+1)^{\text {th }}$ order recurrence relation

$$
\sum_{j=0}^{p+1}(-1)^{j} q^{j(j-1) / 2}\left[\begin{array}{c}
p+1  \tag{3.2}\\
j
\end{array}\right]_{u} x_{n-j}=0
$$

If all of these sequences are $w_{n}$, then it follows that $x_{n}=w_{n}$ obeys (3.2).
It is our aim to give the corresponding generalization of (1.1) for the sequence $w_{n}$; that is, to show there exists coefficients $a_{j}(k, p, u)=a_{j}(k)$ such that

$$
\begin{equation*}
w_{n+k}^{p}=\sum_{j=0}^{p} a_{j}(k) w_{n+j}^{p} \tag{3.3}
\end{equation*}
$$

and to give an explicit form for the $\mathrm{a}_{\mathbf{j}}(\mathrm{k})$. Carlitz [1, Section 3] proved that

$$
D_{p}(w)=\left|w_{n+r+s}^{p}\right| \quad(r, s=0,1, \cdots, p)
$$

is nonzero, showing that the $p+1$ sequences

$$
\left\{w_{n}^{p}\right\},\left\{w_{n+1}^{p}\right\}, \cdots,\left\{w_{n+p}^{p}\right\}
$$

are linearly independent. Reasoning as before, we see these sequences span the space of solutions of (32), so that the expansion (3.3) indeed exists. Putting $k=0,1, \cdots, p$ in (3.3) gives $a_{j}(k)=\delta_{j k}$ for $0 \leq j, k \leq p$. It also follows as before that the sequence

$$
\left\{\mathrm{a}_{\mathrm{j}}(\mathrm{k})\right\}_{\mathrm{k}=0}^{\infty}
$$

satisfies (3.2). Now consider

$$
b_{j}(k, p, u)=b_{j}(k)=u_{k} u_{k-1} \cdots u_{k-p} / u_{k-j}\left(u_{j} u_{j-1} \cdots u_{1} u_{-1} \cdots u_{j-p}\right)
$$

for $j=0,1, \cdots, p-1, b_{p}(k)=\left[\begin{array}{l}k \\ p\end{array}\right]_{u}$, along with the convention $u_{0} / u_{0}=1$. Then $b_{j}(k)=\delta_{j k}$ for $0 \leq j, k \leq p$. Also $\left\{b_{j}(k)\right\}_{k=0}^{\infty}$ obeys (3.2) because it is the product of $p$ sequences each of which obeys (3.1). Since $\left\{a_{j}(k)\right\}_{k=0}^{\infty}$ and $\left\{b_{j}(k)\right\}_{k=0}^{\infty}(j=0,1, \cdots, p)$ obey the same $(p+1)^{\text {th }}$ order recurrence relation and agree in the first $p+1$ values, we have $a_{j}(k)=b_{j}(k)$. Now $a b=a$. so that $u_{-n}=\left(a^{-n}-b^{-n}\right) /(a-b)=-q^{n} u_{n}$. Then

$$
u_{-1} \cdots u_{j-p}=u_{p-j} \cdots u_{1}(-1)^{p-j} q^{(p-j)(p-j+1) / 2}
$$

and thus for $j=0,1, \cdots, p-1$ we see

$$
\begin{align*}
a_{j}(k) & =(-1)^{p-j_{q}}(p-j)(p-j+1) / 2  \tag{3.4}\\
& \left(\frac{u_{k} u_{k-1} \cdots u_{k-p+1}}{u_{p} u_{p-1} \cdots u_{1}}\right)\left(\frac{u_{p} u_{p-1} \cdots u_{1}}{\left(u_{j} \cdots u_{1}\right)\left(u_{p-j} \cdots u_{1}\right)}\right)\left(\frac{u_{k-p}}{u_{k-j}}\right) \\
& =(-1)^{p-j} q_{q}^{(p-j)(p-j+1) / 2}\left[\begin{array}{l}
k \\
p
\end{array}\right]_{u}\left[\begin{array}{c}
p \\
j
\end{array}\right]_{u}\left(u_{k-p} / u_{k-j}\right),
\end{align*}
$$

which is also valid for $j=p$ using the convention $u_{0} / u_{0}=1$. Therefore (3.3) becomes

$$
{\underset{w}{n+k}}_{p}^{p} \sum_{j=0}^{p}(-1)^{p-j} q^{(p-j)(p-j+1) / 2}\left[\begin{array}{l}
k  \tag{3.5}\\
p
\end{array}\right]_{u}\left[\begin{array}{l}
p \\
j
\end{array}\right]_{u}\left(u_{k-p} / u_{k-j}\right) w_{n+j}^{p}
$$

Carlitz has communicated and proved a further extension of this result. Let

$$
x_{n}^{(p)}=w_{n+a_{1}} w_{n+a_{2}} \cdots w_{n+a_{p}}
$$

where the $a_{j}$ are arbitrary but fixed nonnegative integers. Then we have

$$
x_{n+k}^{(p)}=\sum_{j=0}^{p}(-1)^{p-j_{q}(p-j)(p-j+1) / 2}\left[\begin{array}{l}
k  \tag{3.6}\\
p
\end{array}\right]_{u}\left[\begin{array}{l}
p \\
j
\end{array}\right]_{u}\left(u_{k-p} / u_{k-j}\right) x_{n+j}^{(p)}
$$

where $u_{0} / u_{0}$ still applies. We note that putting $a_{1}=a_{2}=\cdots=a_{p}=0$ reduces (3.6) to (3.5).

To prove (3.6) using previous techniques requires us to show that the sequences

$$
\left\{x_{n}^{(p)}\right\},\left\{x_{n+1}^{(p)}\right\}, \cdots,\left\{x_{n+p}^{(p)}\right\}
$$

are linearly independent. To avoid this, we establish (3.6) by induction on $\mathrm{k}_{\text {. }}$ Now (3.6) is true for $k=0$ and all $n$. Assume it is true for some $k \geq 0$ and all $n$, and replace $n$ by $n+1$, giving

$$
\begin{aligned}
x_{n+k+1}^{(p)} & =\left[\begin{array}{l}
k \\
p
\end{array}\right]_{u} \sum_{j=0}^{p}(-1)^{p-j_{q}(p-j)(p-j+1) / 2}\left[\begin{array}{l}
p \\
j
\end{array}\right]_{u} \frac{u_{k-p}}{u_{k-j}} x_{n+j+1}^{(p)} \\
& =\left[\begin{array}{l}
k \\
p
\end{array}\right]_{u} \sum_{j=1}^{p}(-1)^{p-j+1} q^{(p-j+1)(p-j+2) / 2}\left[\begin{array}{c}
p \\
j-1
\end{array}\right]_{u} \frac{u_{k-p}}{u_{k-j+1}} x_{n+j}^{(p)}+\left[\begin{array}{l}
k \\
p
\end{array}\right]_{u} x_{n+p+1}^{(p)} \quad .
\end{aligned}
$$

It follows from (3.2) that

$$
\begin{aligned}
x_{n+p+1}^{(p)} & =-\sum_{j=1}^{p+1}(-1)^{j} q^{j(j-1) / 2}\left[\begin{array}{c}
p+1 \\
j
\end{array}\right]_{u} x_{n+p+1-j}^{(p)} \\
& =\sum_{j=0}^{p}(-1)^{p-j} q^{(p-j)(p-j+1) / 2}\left[\begin{array}{c}
p+1 \\
j
\end{array}\right]_{u} x_{n+j}^{(p)}
\end{aligned}
$$

Thus

$$
\begin{aligned}
& x_{n+k+1}^{(p)}=\left[\begin{array}{l}
k \\
p
\end{array}\right]_{u} \sum_{j=0}^{p}(-1)^{p-j} q^{p-j)(p-j+1) / 2}\left[\begin{array}{c}
p \\
j-1
\end{array}\right]_{u} \frac{x_{n+j}^{(p)}}{u_{j} u_{k-j+1}} \\
& \cdot\left(u_{p+1} u_{k-j+1}-q^{p-j+1} u_{k-p} u_{j}\right) .
\end{aligned}
$$

Since

$$
u_{p+1} u_{k-j+1}-q^{p-j+1} u_{k-p} u_{j}=u_{k+1} u_{p-j+1}
$$

we have

$$
\begin{aligned}
x_{n+k+1}^{(p)} & =u_{k+1}\left[\begin{array}{c}
k \\
p
\end{array}\right]_{u} \sum_{j=0}^{p}(-1)^{p-j_{q}(p-j)(p-j+1) / 2}\left[\begin{array}{c}
p \\
j-1
\end{array}\right]_{u} \frac{u_{p-j+1}}{u_{j} u_{k-j+1}} x_{n+j}^{(p)} \\
& =\left[\begin{array}{c}
k+1 \\
p
\end{array}\right] \sum_{j=0}^{p}(-1)^{p-j_{q}}(p-j)(p-j+1) / 2\left[\begin{array}{l}
p \\
j
\end{array}\right]_{u}^{\frac{u_{k-p+1}}{u_{k-j+1}} x_{n+j}^{(p)},}
\end{aligned}
$$

completing the induction step and the proof.

## 4. SPECIAL CASES

In this section we reduce (3.5) to a general Fibonacci power identity and to an identity involving powers of terms of an arithmetic progression. First if we let $w_{n}=F_{n s+r}, u_{n}=F_{n s}$, where $r$ and $s$ are fixed integers with $s \neq 0$, then both $w_{n}$ and $u_{n}$ satisfy

$$
\begin{equation*}
\mathrm{y}_{\mathrm{n}+2}-\mathrm{L}_{\mathrm{s}} \mathrm{y}_{\mathrm{n}+1}+(-1)^{\mathrm{s}} \mathrm{y}_{\mathrm{n}}=0 \tag{4.1}
\end{equation*}
$$

The roots of the auxiliary polynomial of (4.1) are distinct for $s \neq 0$, so that $w_{n}$ and $u_{n}$ satisfy the conditions of the previous section. In this case the $u$ generalized binomial coefficients $\left[\begin{array}{c}\mathrm{m} \\ \mathrm{r}\end{array}\right]_{\mathrm{u}}$ become the s-generalized Fibonacci coefficients $\left[\begin{array}{c}\mathrm{m} \\ \mathrm{t}\end{array}\right]_{\mathrm{S}}$ defined by

$$
\left[\begin{array}{l}
m \\
t
\end{array}\right]_{S}=\frac{F_{m s}{ }^{F}(m-1) s^{\cdots} \cdot F_{(m-t+1) s}}{F_{t s} F_{t s-\infty} \cdots F_{s}}(t>0):\left[\begin{array}{c}
m \\
0
\end{array}\right]_{S}=1
$$

A recurrence relation for these coefficients is given in［3］．Now here

$$
q=(-1)^{s} \text {, so }(-1)^{p-j}{ }_{q}(p-j)(p-j+1) / 2 \quad=(-1)^{(p-j)[s(p-j+1)+2] / 2} .
$$

Then（3．5）yields
（4．3）$\quad F_{(n+k) s+r}^{p}=\sum_{j=0}^{p}(-1)^{(p-j)[s(p-j+1)+2] / 2}\left[\begin{array}{l}k \\ p\end{array}\right]_{S}\left[\begin{array}{l}p \\ \frac{F_{-j}}{F_{(k-p) s}}{ }_{(k-j) s} F_{(n+j) s+r}^{p} . ~\end{array}\right.$

Putting $s=1$ and $r=0$ gives equation（2．2）．
On the other hand，if we let $w_{n}=n s+r$ and $u_{n}=n$ ，where $r$ and $s$ are fixed integers，then $w_{n}$ and $u_{n}$ obey

$$
\begin{equation*}
\mathrm{y}_{\mathrm{n}+2}-2 \mathrm{y}_{\mathrm{n}+1}+\mathrm{y}_{\mathrm{n}}=0 \tag{4.4}
\end{equation*}
$$

Since the characteristic polynomial of（4．4）has the double root $\mathrm{x}=1$ ，both $w_{n}$ and $\dot{u}_{n}$ satisfy the conditions for the validity of（3．5）．In this case we have $\mathrm{q}=1$ and $\left[\begin{array}{c}\mathrm{m} \\ \mathrm{t}\end{array}\right]_{\mathrm{u}}=\binom{\mathrm{m}}{\mathrm{t}}$ ，the usual binomial coefficient．Then（3．5）becomes

$$
\begin{equation*}
([n+k] s+r)^{p}=\sum_{j=0}^{p}(-1)^{p-j}\binom{k}{p}\binom{p}{j}\left(\frac{k-p}{k-j}\right) \quad([n+j] s+r)^{p} \tag{4.5}
\end{equation*}
$$

This reduces to $(2.3)$ by setting $s=1$ and $r=0$ 。

## REQUEST

The Fibonacci Bibliographical Research Center desires that any reader finding a Fibonacci reference send a card giving the reference and a brief description of the contents. Please forward all such information to:
Fibonacci Bibliographical Research Center, Mathematics Department,
San Jose State College,
San Jose, California.

The Fibonacci Association invites Educational Institutions to apply for Academic Membership in the Association. The minimum subscriptionfee is $\$ 25$ annually. (Academic Members will receive two copies of each issue and will have their names listed in the Journal.

# ELEMENTARY PROBLEMS AND SOLUTIONS 

Edited by A.P. Hillman, University of New Mexico, Albuquerque, New Mex.

Send all communications regarding Elementary Problems and Solutions to Professor A. P. Hillman, Department of Mathematics and Statistics, University of New Mexico, Albuquerque, New Mexico 87106. Each problem or solution should be submitted in legible form, preferably typed in double spacing, on a separate sheet or sheets, in the format used below. Solutions should be received within three months of the publication date.

## B-94 Proposed by Clyde A. Bridger, Springfield Jr. College, Springfield, Ill

Show that the number $N_{n}$ of non-zero terms in the expansion of

$$
K_{n}=\left|\begin{array}{ccccccccc}
a_{1} & b_{1} & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\
-1 & a_{2} & b_{2} & 0 & 0 & \cdots & 0 & 0 & 0 \\
0 & -1 & a_{3} & b_{3} & 0 & \cdots & 0 & 0 & 0 \\
\cdots & & & & & & & & \\
\cdots & & & & & & & & \\
\cdots & & & & & 0 & -1 & a_{n-1} & b_{n-1} \\
0 & 0 & 0 & \cdots & 0 & 0 & 0 & -1 & a_{n} \\
0 & 0 & 0 & \cdots & 0 & & & &
\end{array}\right|
$$

is obtained by replacing each $a_{i}$ and each $b_{i}$ by 1 and evaluating $K_{n}$. Show further that $N_{n}=F_{n+1}$, the ( $n+1$ )st Fibonacci number.

## B-95 Proposed by Brother U. Alfred, St. Mary's College, Calif.

What is the highest power of 2 that exactly divides

$$
\mathrm{F}_{1} \mathrm{~F}_{2} \mathrm{~F}_{3} \cdots \mathrm{~F}_{100} \quad ?
$$

## B-96 Proposed by Phil Mana, University of New Mexico, Albuquerque, New Mex.

Let $G_{n}$ be the number of ways of expressing the positive integer $n$ as an ordered sum $a_{1}+a_{2}+\cdots+a_{S}$ with each $a_{i}$ in the set $\{1,2,3\}$. (For
example, $\mathrm{G}_{3}=4$ since 3 has just the expressions $3,2+1,1+2,1+1+1$.) Find and prove the lowest order linear homogeneous recursion relation satisfied by the $G_{n}$.

B-97 Proposed by Douglas Lind, Universify of Virginia, Charlotfesville, Va.

Let $A=\left\{a_{k}\right\}_{k=1}^{\infty}$ be an increasing sequence of numbers and let $A(n)$ denote the number of terms of $A$ not greater than $n$. The Schnirelmann density of $A$ is defined as the greatest lower bound of the ratios $A(n) / n$ for $n=1$, $2, \cdots$. Show that the Fibonacci sequence has density zero.

B-98 Proposed by Douglas Lind, University of Virginia, Charlottesville, Va.
Let $F_{n}$ be the $n^{\text {th }}$ Fibonacci number and find a compact expression for the sum $S_{n}(x)=F_{1} x+F_{2} x^{2}+F_{3} x^{3}+\cdots+F_{n} x^{n}$ 。

## B-99 Proposed by Douglas Lind, University of Virginia, Charlottesville, Va.

Find a compact expression for the infinite sum

$$
T(x)=S_{1}(x)+\frac{S_{2}(x)}{2!}+\frac{S_{3}(x)}{3!}+\cdots,
$$

where $S_{n}(x)$ is as defined in B-98.

## SOLUTIONS

DIFFERENCE AND DIFFERENTIAL EQUATIONS

B-76 Proposed by James A. Jeske, San Jose State College, San Jose, Calif.

The recurrence relation for the sequence of Lucas numbers is $L_{n+2}-$ $\mathrm{L}_{\mathrm{n}+1}-\mathrm{L}_{\mathrm{n}}=0$ with $\mathrm{L}_{1}=1, \mathrm{~L}_{2}=3$ 。

Find the transformed equation, the exponential generating function, and the general solution.

## Solution by Douglas Lind, University of Virginia, Charloftesville, Va.

By (4.2) of Jeske's article, the transformed equation is

$$
L_{2}(D) Y=Y^{\prime \prime}-Y^{\prime}-Y=0, \quad Y(0)=2, \quad Y^{\prime}(0)=1
$$

Now $r_{1}=(1+\sqrt{5}) / 2$ and $r_{2}=(1-\sqrt{5}) / 2$ are the roots of $L_{2}(r)=0$, hence with the given initial values we may determine the solution for the Lucas sequence to be

$$
\mathrm{L}_{\mathrm{n}}=\left(\frac{1+\sqrt{5}}{2}\right)^{\mathrm{n}}+\left(\frac{1-\sqrt{5}}{2}\right)^{\mathrm{n}}
$$

The exponential generating function for the Lucas sequence is thus

$$
Y(t)=e^{r_{1} t}+e^{r_{2} t}=\sum_{n=0}^{\infty} L_{n} \frac{t^{n}}{n_{!}^{!}}
$$

Also solved by Clyde A. Bridger, Howard L. Walton, and the Proposer.

## IT PAYS TO CHECK

## B-77 Proposed by James A. Jeske, San Jose State Colle ge, San Jose, Calif.

Find the general solution and the exponential generating function for the recurrence relation

$$
\mathrm{y}_{\mathrm{n}+3}-5 \mathrm{y}_{\mathrm{n}+2}+8 \mathrm{y}_{\mathrm{n}+1}-4 \mathrm{y}_{\mathrm{n}}=0
$$

with $\mathrm{y}_{0}=0, \mathrm{y}_{1}=0$, and $\mathrm{y}_{2}=-1$.

## Solution by Douglas Lind, University of Virginia, Charloftesville, Va.

Since $L_{3}(x)=x^{3}-5 x^{2}+8 x-4=(x-1)(x-2)(x-2)=0$, we have, using the notation of section 4 of Jeske's paper, $r_{1}=1, m_{1}=1, r_{2}=2$,
$\mathrm{m}_{2}=2$, and $\mathrm{m}=2$. With the given initial values we find the exponential generating function to be

$$
Y(t)=-e^{t}+e^{2 t}(1-t)
$$

which, by applying the inverse transform (3.3), yields the general solution as

$$
\mathrm{y}_{\mathrm{n}}=2^{\mathrm{n}}\left(1-\frac{\mathrm{n}}{2}\right)-1
$$

Also solved by Clyde A. Bridger and the Proposer. Douglas Lind also noted that formula (4.8) of Jeske's paper is not correct.

## A LUCAS SUM

## B-78 Proposed by Douglas Lind, Universify of Virginia, Charlottesville, Va.

Show that

$$
\mathrm{F}_{\mathrm{n}}=\mathrm{L}_{\mathrm{n}-2}+\mathrm{L}_{\mathrm{n}-6}+\cdots+\mathrm{L}_{\mathrm{n}-2-4 \mathrm{~m}}+\mathrm{e}_{\mathrm{n}}, \mathrm{n}>2,
$$

where $m$ is the greatest integer in $(n-3) / 4$, and $e_{n}=0$ if $n \equiv 0(\bmod 4)$, $e_{n}=1$ if $n \neq 0(\bmod 4)$.

## Solution by the Proposer.

Proof by induction: The proposition is easily shown true for $n=3,4,5,6$. Now assume the theorem true for $3 \leq n \leq k+3$. Then one finds that

$$
\mathrm{F}_{\mathrm{k}+4}=\mathrm{L}_{\mathrm{k}+2}+\mathrm{F}_{\mathrm{k}}=\mathrm{L}_{\mathrm{k}+2}+\left(\mathrm{L}_{\mathrm{k}-2}+\mathrm{L}_{\mathrm{k}-6}+\cdots+\mathrm{L}_{\mathrm{k}-2-4 \mathrm{~m}}+\mathrm{e}_{\mathrm{k}}\right)
$$

so that the theorem is true for $k+4$, completing the induction step and the proof.

## Also solved by David Zeiflin.

B-79 Proposed by Brother U. Alfred, St. Mary's College, Calif.
Let $\mathrm{a}=(1+\sqrt{5}) / 2$. Determine a closed expression for

$$
X_{n}=[a]+\left[a^{2}\right]+\cdots+\left[a^{n}\right],
$$

where the square brackets mean "greatest integer in."

## Solution by the Proposer.

If $b=(1-\sqrt{5}) / 2, a^{k}=L_{k}-b^{k}$ with $b$ negative and $|b|<1$ 。Hence $\left[\mathrm{a}^{\mathrm{k}}\right]=\mathrm{L}_{\mathrm{k}}$ if k is odd and $\left[\mathrm{a}^{\mathrm{k}}\right]^{\mathrm{k}}=\mathrm{L}_{\mathrm{k}}-1$ if k is even. It follows that

$$
X_{n}=\sum_{k=1}^{n} L_{k}-\left[\frac{n}{2}\right]=L_{n+3}-3-\left[\frac{n}{2}\right]
$$

Also solved by J.L. Brown, Jr. and Jeremy C. Pond.

## OUR MAN OF PISA

B-80 Proposed by Maxey Brooke, Sweeny, Texas.
Solve the division alphametic

$$
\text { FIB } \frac{\mathrm{PISA}}{\mathrm{XONACCI}}
$$

where each letter represents one of the nine digits $1,2, \cdots, 9$ and two letters may represent the same digit.

Solution by the Proposer.
$3 8 2 \longdiv { 3 7 6 4 2 2 8 }$

This solution may not be unique.

## GAUSSIAN PRIMES

## B-81 Proposed by Douglas Lind, University of Virginia, Charlottesville, Va.

Prove that only one of the Fibonacci numbers $1,2,3,5, \cdots$ is a prime in the ring of Gaussian integers.

Solution by L. Carlitz, Duke University, Durham, N.C.

Since

$$
F_{2 n+1}=F_{n+1}^{2}+F_{n}^{2}=\left(F_{n+1}+F_{n} i\right)\left(F_{n+1}-F_{n} i\right)
$$

it follows that $F_{2 n+1}$ is composite in the Gaussian ring for all $n>0$. Since $F_{2 n}=F_{n} L_{n}$ it follows that $F_{2 n}$ is composite in the ring of integers (and therefore in the Gaussian ring) for $n>2$. For $n=2, F_{4}=3$; for $n=1$, $\mathrm{F}_{2}=1$ 。

Also solved by Sidney Kravitz and the proposer.

## NOTICE TO ALL SUBSCRIBERS: ! !

Please notify the Managing Editor AT ONCE of any address change. The Post Office Department, rather than forwarding magazines mailed third class, sends them directly to the dead-letter office. Unless the addressee specifically requests the Fibonacci Quarterly to be forwarded at first class rates to the new address, he will not receive it. (This will usually cost about 30 cents for firstclass postage.) If possible, please notify us AT LEAST THREE WEEKS PRIOR to publication dates: February 15, April 15, October 15, and December 15.

[^0]:    * He has a misprint, making the greatest power of 2 too small by one.
    **The sequence is $D_{\mathrm{n}}=\left(\alpha^{\mathrm{n}}-\beta^{\mathrm{n}}\right) /(\alpha-\beta)$, where $\alpha+\beta$ and $\alpha \beta$ are mutually prime integers. For $\mathrm{F}_{\mathrm{n}}$, by (4); $\alpha=(1 / 2)(1+\sqrt{5})$ and $\beta=(1 / 2)(1-\sqrt{5})$.
