## 1. INTRODUCTION

We define the Fibonacci numbers as usual by means of

$$
\mathrm{F}_{0}=0, \quad \mathrm{~F}_{1}=1, \quad \mathrm{~F}_{\mathrm{n}+1}=\mathrm{F}_{\mathrm{n}}+\mathrm{F}_{\mathrm{n}-1} \quad(\mathrm{n} \geq 1)
$$

It is known that every positive integer N can be written in the form

$$
\begin{equation*}
\mathrm{N}=\mathrm{F}_{\mathrm{k}_{1}}+\mathrm{F}_{\mathrm{k}_{2}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}} \tag{1.1}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{k}_{1}>\mathrm{k}_{2}>\ldots>\mathrm{k}_{\mathrm{r}} \geq 2 \tag{1.2}
\end{equation*}
$$

and $r$ depends on $N$. We call (1.1) a Fibonacci representation of N. Moreover by the theorem of Zeckendorf, the representation (1.1) is unique provided the $\mathrm{k}_{\mathrm{j}}$ satisfy the inequalities
(1.3) $\mathrm{k}_{\mathrm{j}}-\mathrm{k}_{\mathrm{j}+1} \geq 2 \quad(\mathrm{j}=1,2, \cdots, r-1) ; \quad \mathrm{k}_{\mathrm{r}} \geq 2$.

Such a representation may be called the canonical representation of $N$.
Now let $A_{k}$ denote the set of positive integers $\{N\}$ for which $k_{r}=k$. Then it is clear that the

$$
\mathrm{A}_{\mathrm{k}} \quad(\mathrm{k}=2,3,4, \cdots)
$$

[^0]constitute a partition of the set of positive integers. The chief object of the present paper is to describe the numbers in $A_{k}$ in terms of the greatest integer function. We shall show that
(1.4) $\quad A_{2 t}=\left\{a b^{t-1} a(n) \mid n=1,2,3, \cdots\right\} \quad(t=1,2,3, \cdots)$,
(1.5) $\quad A_{2 t+1}=\left\{b^{t} a(n) \mid n=1,2,3, \cdots\right\} \quad(t=1,2,3, \cdots)$,
where
(1.6) $\mathrm{a}(\mathrm{n})=[\alpha \mathrm{n}], \quad \mathrm{b}(\mathrm{n})=\left[\alpha^{2} \mathrm{n}\right], \quad \alpha=(1+\sqrt{5}) / 2$
and $[\mathrm{x}$ ] denotes the greatest integer $\leq \mathrm{x}$. As is customary, powers and juxtaposition of functions should be interpreted as composition.

Moreover, we shall show that

$$
\begin{aligned}
& A(2 t, \overline{2 t+2})=\left\{a b^{t-1} a^{2}(n) \mid n=1,2,3, \cdots\right\} \\
& A(2 t, 2 t+2)=\left\{a b^{t-1} a b(n) \mid n=1,2,3, \cdots\right\} \\
& A(2 t+1, \overline{2 t+3})=\left\{b^{t} a^{2}(n) \mid n=1,2,3, \cdots\right\} \\
& A(2 t+1,2 t+3)=\left\{b^{t} a b(n) \mid n=1,2,3, \cdots\right\},
\end{aligned}
$$

where $A(s, s+2)$ denotes the set of positive integers with canonical representation

$$
\mathrm{F}_{\mathrm{k}_{1}}+\ldots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{\mathrm{s}+2}+\mathrm{F}_{\mathrm{s}}
$$

while $A(s, \overline{s+2})$ denotes the set with canonical representation

$$
\mathrm{F}_{\mathrm{k}_{1}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{\mathrm{s}} \quad\left(\mathrm{k}_{\mathrm{r}}>\mathrm{s}+2\right)
$$

Using any Fibonacci representation of N

$$
\mathrm{N}=\mathrm{F}_{\mathrm{k}_{1}}+\mathrm{F}_{\mathrm{k}_{2}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}
$$

$$
\begin{equation*}
\mathrm{e}(\mathbb{N})=\mathrm{F}_{\mathrm{k}_{1}-1}+\mathrm{F}_{\mathrm{k}_{2}-1}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}^{-1}}} \tag{1.7}
\end{equation*}
$$

The fact that $e(N)$ is independent of the Fibonacci representation chosen for $N$ was proved in [2].

The following theorems, which will be used in Section 4, were also established in [2].

Theorem 1. For every $N, e(N+1) \geq e(N)$ with equality if and only if N is in $\mathrm{A}_{2}$. (See [2], p. 216, Theorem 5 and proof.)

Theorem 2. If $N$ is in $A_{2}$ then neither $N-1$ nor $N+1$ is in $A_{2}$. (See [2], p. 217, comments following Theorem 5.)

## 2. THE ARRAY R

As in [3] we form the 3-rowed array $R$ as follows: In the first row we put the positive integers in natural order. We begin the second row with 1. To get an entry of the third row, we add the entries appearing above it in the first and second rows. We get further entries in the second row by choosing the smallest integer which has not appeared so far in the second or third rows.

| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | $\cdots$ |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 1 | 3 | 4 | 6 | 8 | 9 | 11 | 12 | 14 | 16 | $\cdots$ |
| 2 | 5 | 7 | 10 | 13 | 15 | 18 | 20 | 23 | 26 | $\cdots$ |

Note that R is uniquely determined by the following properties:
(2.2) Every positive integer appears exactly once in row 2 or row 3.
(2.3) Each row is a monotone sequence.
(2.4) The sum of the first two rows is the third row.

Now also consider the 3 -rowed array $R^{\prime}$ 。

| 1 | 2 | 3 | 4 | $\cdots$ |
| :---: | :---: | :---: | :---: | :---: |
| $a(1)$ | $a(2)$ | $a(3)$ | $a(4)$ | $\cdots$ |
| $b(1)$ | $b(2)$ | $b(3)$ | $b(4)$ | $\cdots$ |

where $a(n), b(n)$ are defined by (1.6). Since $\alpha+1=\alpha^{2}$, properties (2.3) and (2.4) are obviously satisfied by $\mathrm{R}^{\prime}$. To see that every number appears in $R^{\prime}$, let $N \geq 2$ be arbitrary. We will show that either $a([N / \alpha])$ or $\mathrm{b}\left(\left[\mathrm{N} / \alpha^{2}\right]\right)$ is $\mathrm{N}-1$. Suppose not. Then they are both too small; that is,

$$
\alpha[\mathrm{N} / \alpha]<\mathrm{N}-1
$$

and

$$
\alpha^{2}\left[\mathrm{~N} / \alpha^{2}\right]<\mathrm{N}-1
$$

Dividing the first inequality by $\alpha$, the second by $\alpha^{2}$, remembering that

$$
\frac{1}{\alpha}+\frac{1}{\alpha^{2}}=1
$$

and adding, we get

$$
[\mathrm{N} / \alpha]+\left[\mathrm{N} / \alpha^{2}\right]<\mathrm{N}-1
$$

But this is a contradiction since $\mathrm{N} / \alpha+\mathrm{N} / \alpha^{2}=\mathrm{N}$.
Now to see that the ranges of $a$ and $b$ are disjoint, suppose for some numbers $N, M$ and $P$, we had $a(N)=b(M)=P$. Then

$$
\alpha \mathrm{N}-1<\mathrm{P}<\alpha \mathrm{N}
$$

and

$$
\alpha^{2} \mathrm{M}-1<\mathrm{P}<\alpha^{2} \mathrm{M}
$$

Again dividing and adding, we get

$$
N+M-1<P<N+M
$$

a contradiction. The fact that no number appears twice in the same row follows simply because both $\alpha$ and $\alpha^{2}$ are greater than 1. Note that (2.2) was proved using only the fact that $\alpha$ and $\alpha^{2}$ are irrational and

$$
\frac{1}{\alpha}+\frac{1}{\alpha^{2}}=1
$$

The result is not new, of course.
We have established that $R=R^{\prime}$.

## 3. SOME PROPERTIES OF $a(n)$ AND $b(n)$

In this section we prove several equalities involving the functions $a(n)$ and $\mathrm{b}(\mathrm{n})$. In our proof we use only the properties (2.2), (2.3) and (2.4) of $R\left(=R^{\prime}\right)$ from Section 2. Of course, the equalities could, with much more effort, be proved from the definitions (1.6).

$$
\begin{equation*}
a(\mathrm{~N})+\mathrm{b}(\mathrm{~N})=\mathrm{a}(\mathrm{~b}(\mathrm{~N})) \tag{3.5}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{b}^{2}(\mathbb{N})=\mathrm{aba}(\mathrm{~N})+2 \tag{3.6}
\end{equation*}
$$

$$
\begin{equation*}
a b^{2}(N)=b^{2} a(N)+3 \tag{3.7}
\end{equation*}
$$

$$
\begin{array}{cl}
\mathrm{b}^{\mathrm{r}(\mathrm{~N})}=\mathrm{ab}{ }^{\mathrm{r}-1} \mathrm{a}(\mathrm{~N})+\mathrm{F}_{2 \mathrm{r}-1} & (\mathrm{r}=1,2, \cdots) \\
\mathrm{ab}^{\mathrm{r}(\mathrm{~N})}=\mathrm{b}^{\mathrm{r}} \mathrm{a}(\mathrm{~N})+\mathrm{F}_{2 \mathrm{r}} & (\mathrm{r}=1,2, \cdots) \\
\mathrm{b}^{\mathrm{r}(1)}=\mathrm{F}_{2 \mathrm{r}+1} & (\mathrm{r}=1,2, \cdots) . \tag{3.10}
\end{array}
$$

Proof. Equation (3.1) is (2.4). For (3.2), note that in R, in the third row, to $b(N)$, or the second row to $a(J)=b(N)-1$, occur all the numbers $1,2, \cdots, b(N)$. Hence $J+N=b(N)$. Therefore, by (3.1) $J=a(N)$; that is, $a(a(N))=b(N)-1$. Equation (3.3) comes from (3.1) and (3.2). To prove (3.4), note that $b(a(N))$ is the $a(N)^{\text {th }}$ entry in the third row of $R$, and $a(b(N))$ is the $b(N)^{\text {th }}$ entry in the second row. Then the total number of entries is $a(N)+b(N)=b(a(N))+1$. Hence $b(a(N))$ cannot be the largest so $a(b(N))$ must be and every integer $\leq b(a(N))+1$ must have appeared. Hence $a(b(N))=b(a(N))+1$. Equation (3.5) is obvious from (3.3) and (3.4). Equation (3.6) is obtained by adding (3.2) and (3.4) and using (3.1) and (3.5). Similarly we get (3.7) by adding (3.4) and (3.6). Equations (3.8) and (3.9) arise by induction. If we set $N=1$ in (3.8) we get

$$
\mathrm{b}\left(\mathrm{~b}^{\mathrm{r}-1}(1)\right)=\mathrm{a}\left(\mathrm{~b}^{\mathrm{r}-1}(1)\right)+\mathrm{F}_{2 \mathrm{r}-1}
$$

so, by (3.1),

$$
\mathrm{b}^{\mathrm{r}-1}(1)=\mathrm{F}_{2 \mathrm{r}-1}
$$

## 4. THE SETS $A_{k}$

We begin with some preliminary theorems.
Theorem 3. If $N$ is in $A_{2}$, then $N+1$ is in $A_{k}$ with $k$ odd. Proof. By Theorem 2,

$$
\begin{equation*}
\mathrm{N}+1=\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{\mathrm{k}_{\mathrm{r}-1}}+\cdots+\mathrm{F}_{\mathrm{k}_{1}} \quad \mathrm{k}_{\mathrm{r}}>2 \tag{4.1}
\end{equation*}
$$

For convenience we let

$$
\mathrm{N}^{\prime}=\mathrm{F}_{\mathrm{k}_{\mathrm{r}-1}}+\cdots+\mathrm{F}_{\mathrm{k}_{1}}
$$

Then

$$
\begin{aligned}
\mathrm{N}+1 & =\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{N}^{\gamma}=\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-2}+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-1}+\mathrm{N}^{\mathrm{r}} \\
& =\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-4}+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-3}+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-1}+\mathrm{N}^{\gamma}
\end{aligned}
$$

Continuing, we see that $N+1$ is either

$$
\mathrm{F}_{3}+\mathrm{F}_{4}+\mathrm{F}_{6}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-1}+\mathrm{N}^{1}
$$

or

$$
\mathrm{F}_{2}+\mathrm{F}_{3}+\mathrm{F}_{5}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-1}+\mathrm{N}^{\prime}
$$

If the latter, N would be in $\mathrm{A}_{3}$. Hence

$$
\mathrm{N}=\mathrm{F}_{2}+\mathrm{F}_{4}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}-1}+\mathrm{N}^{\prime}
$$

and $\mathrm{k}_{\mathrm{r}}$ is odd.
Theorem 4. If $N$ and $M$ are in $A_{2}$ and $e(e(N))=e(e(M))$, then $\mathrm{N}=\mathrm{M}$.

Proof. Suppose $N \neq M$. If $e(N)=e(M)$ then by Theorem 1, $N$ and $M$ are consecutive integers and by Theorem 2 could not both be in $A_{2}$. So suppose $e(N)<e(M)$. Then by Theorem 1 , $e(N)$ is in $A_{2}$ and $e(M)=$ $e(N)+1$. Hence by Theorem 3, $e(M)$ is in $A_{k_{r}}$ with $k_{r}$ odd:

$$
\mathrm{e}(\mathrm{M})=\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{\mathrm{k}_{\mathrm{r}-1}}+\cdots \quad\left(\mathrm{k}_{\mathrm{r}} \text { odd }\right)
$$

Let

$$
\mathrm{P}=\mathrm{F}_{\mathrm{k}_{\mathrm{r}}+1}+\mathrm{F}_{\mathrm{k}_{\mathrm{r}-1}+1}+\cdots
$$

Now $e(P)=e(M)$, but $P$ is in $A_{k_{r}+1}$ so $P \neq M$. Hence, by Theorem 1 we must have $P=M+1$. Hence $k_{r}$ is odd, a contradiction. This proves the theorem.

Theorem 5. Let $Q_{j}$ be the $j^{\text {th }}$ largest number in $A_{2}$. Then

$$
e\left(e\left(Q_{j}\right)\right)=j
$$

Proof. We can easily see by induction that there are exactly $F_{n-1}$ numbers in $A_{2}$ whose canonical representations involve only $F_{2}, F_{3}, \ldots$, $F_{n}$, for let $C_{n}$ be that set of numbers; i. e., $N \in C_{n}$ if and only if

$$
\mathrm{N}=\mathrm{F}_{2}+\cdots+\mathrm{F}_{\mathrm{k}_{1}} \quad\left(\mathrm{k}_{1} \leq \mathrm{n}\right)
$$

We want to show that card $\left(C_{n}\right)=F_{n-1}$ and that if $N \in C_{n}, \quad N<$ $\mathrm{F}_{\mathrm{n}+1^{\circ}}$. This is easily checked for small n . Suppose it is true up to n . Then

$$
C_{n+1}=C_{n} \cup\left(C_{n-1}+F_{n+1}\right)
$$

Since this union is disjoint, by the induction hypothesis, the conclusion follows readily.

The point is that $1+F_{n+1}(n>3)$ is the $\left(1+F_{n-1}\right)^{\text {th }}$ number in $A_{2}$. But

$$
e\left(e\left(1+F_{n+1}\right)\right)=1+F_{n-1}
$$

i. e., the value of $e(e(\cdot))$ on the $\left(1+F_{n-1}\right)^{\text {th }}$ number of $A_{2}$ is $1+F_{n-1}$.

Hence, since $e(e(\cdot))$ is monotone and $1-1$ on $A_{2}$ (Theorems 1 and 4), we see that $e(e(\cdot))$ simply counts the members of $A_{2}$; that is,

$$
\mathrm{e}\left(\mathrm{e}\left(\mathrm{Q}_{\mathrm{j}}\right)\right)=\mathrm{j}
$$

Now let $N_{i}$ be defined by the requirements

$$
\begin{equation*}
e\left(N_{i}\right)=i, \quad e\left(N_{i}-1\right) \neq i \tag{4.3}
\end{equation*}
$$

(Set $\mathrm{e}(0)=0$, so that $\mathrm{N}_{1}=1, \mathrm{~N}_{2}=3$, etc.)

Theorem 6. For any $N, e(a(N))=N$ and $e(b(N))=a(n)$. The numbers $\left(N_{1}, N_{2}, \ldots\right)$ and $\left(Q_{1}+1, Q_{2}+1, \ldots\right)$ are the second and third rows of the array $R_{1}$.

Proof. Note that by Theorem 1, e(( $\left.\left.\mathrm{Q}_{\mathrm{i}}+1\right)-1\right)=e\left(\mathrm{Q}_{\mathrm{i}}+1\right)$ so that the sets $\left\{N_{i}\right\}$ and $\left\{Q_{i}+1\right\}$ are disjoint. Furthermore, again by Theorem 1 , together they exhaust all positive integers. Now to establish the theorem we only have to show property (2.4) of Section 2 and then that $e\left(Q_{j}+1\right)=N_{j}$ 。 Suppose for some j that the latter is false. Then, since

$$
\mathrm{e}\left(\mathrm{e}\left(\mathrm{Q}_{\mathrm{j}}+1\right)\right)=\mathrm{e}\left(\mathrm{e}\left(\mathrm{Q}_{\mathrm{j}}\right)\right)=\mathrm{j}=\mathrm{e}\left(\mathrm{~N}_{\mathrm{j}}\right)
$$

we must have

$$
e\left(Q_{j}+1\right)=N_{j}+1
$$

(since $e\left(N_{j}-1\right) \neq j$, by (4.3)). Furthermore $N_{j}$ must be in $A_{2}$. Therefore $e\left(Q_{j}+1\right) \in A_{k_{r}}, k_{r}$ odd, so that

$$
\mathrm{e}\left(\mathrm{Q}_{\mathrm{j}}+1\right)=\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\cdots+\mathrm{F}_{\mathrm{k}_{1}} \quad\left(\mathrm{k}_{\mathrm{r}} \text { odd }\right)
$$

But then

$$
\mathrm{Q}_{\mathrm{j}}+1=\mathrm{F}_{\mathrm{k}_{\mathrm{r}}+1}+\cdots+\mathrm{F}_{\mathrm{k}_{1}+1} \quad\left(\mathrm{k}_{\mathrm{r}}+1 \text { even }\right)
$$

Theorem 3 implies that $Q_{j}$ is not in $A_{2}$, a contradiction. Hence $e\left(Q_{j}+1\right)$ $=N_{j}$.

Now suppose

$$
\mathrm{N}_{\mathrm{j}}=\mathrm{F}_{\mathrm{k}_{\mathrm{s}}}+\mathrm{F}_{\mathrm{k}_{\mathrm{s}-1}}+\cdots+\mathrm{F}_{\mathrm{k}_{1}}
$$

is the canonical representation of $N_{j}$. Then, since $Q_{j}+1$ is not in $A_{2}$,

$$
\mathrm{Q}_{\mathrm{j}}+1=\mathrm{F}_{\mathrm{k}_{\mathrm{s}}+1}+\mathrm{F}_{\mathrm{k}_{\mathrm{S}-1}+1}+\cdots+\mathrm{F}_{\mathrm{k}_{1}+1}
$$

so that

$$
\begin{equation*}
j+N_{j}=e\left(N_{j}\right)+N_{j}=Q_{j}+1 \tag{4.4}
\end{equation*}
$$

This proves the theorem.
Theorem 7. We have $A_{2}=a^{2}$ (N) where $\mathbb{N}$ is the set of positive integers. Further,

$$
\begin{equation*}
A_{2 t+1}=b^{t} a(\mathbb{N}) \quad(t=1,2,3, \cdots) \tag{4.5}
\end{equation*}
$$

and

$$
\begin{equation*}
A_{2 t}=a b^{t-1} a(\text { 塂 }) \quad(t=1,2,3, \cdots) . \tag{4.6}
\end{equation*}
$$

Proof. We have seen that for any $N$,

$$
\mathrm{e}(\mathrm{~b}(\mathrm{~N}))=\mathrm{e}\left(\mathrm{a}^{2}(\mathrm{~N})\right)=\mathrm{a}(\mathrm{~N})
$$

Hence since $b(N) \neq a^{2}(N)$ and $Q_{N}+1=b(N)$, we get $Q_{N}=a^{2}(N)$. This shows that $A_{2}=a^{2}(\mathbb{N})$. Now suppose $N$ is in $A_{3}$. Then $e(N)$ is in $A_{2}$ and $e(N)=a^{2}(M)$ for some $M$. Hence $N$ is either ba(M) or $a^{3}(M)$. The latter is impossible since $N$ is in $A_{3}$, not $A_{2}$. Hence $A_{3}=b a(1)$.

Continuing in this way, we complete the proof of the theorem by induction.

## 5. SOME ADDITIONAL PROPERTIES

Since

$$
\begin{equation*}
\mathbb{N}=a(\mathbb{N}) \cup b(\mathbb{N}) \tag{5.1}
\end{equation*}
$$

it follows from Theorem 7 that

$$
\begin{equation*}
a(N)=\bigcup_{t=1}^{\infty} A_{2 t} \tag{5.2}
\end{equation*}
$$

and

$$
\begin{equation*}
b(\mathbb{N})=\bigcup_{t=1}^{\infty} A_{2 t+1} \tag{5.3}
\end{equation*}
$$

Again, by (5.1)

$$
\begin{equation*}
a^{2}(\mathbb{N})=a^{2}(\mathbb{N}) \cup a^{2} b(\mathbb{N}) \tag{5.4}
\end{equation*}
$$

By (3.2)

$$
a^{3}(n)=b a(n)-1
$$

Since, by (4.5),

$$
\begin{equation*}
\mathrm{ba}(\mathbb{N})=\mathrm{A}_{3} \tag{5.5}
\end{equation*}
$$

it follows that

$$
\begin{equation*}
\mathrm{a}^{3}(\mathbb{N})=\mathrm{A}(2, \overline{4}) \tag{5.6}
\end{equation*}
$$

where the right member denotes the set of positive integers with canonical representation

$$
\mathrm{F}_{\mathrm{k}_{1}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{2} \quad\left(\mathrm{k}_{\mathrm{r}}>4\right)
$$

Thus by (5.4), we have

$$
\begin{equation*}
\mathrm{a}^{2} \mathrm{~b}(\mathbb{N})=\mathrm{A}(2,4) \tag{5.7}
\end{equation*}
$$

where the right member denotes the set of positive integers with canonical representation

$$
\mathrm{F}_{\mathrm{k}_{1}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{4}+\mathrm{F}_{2} \quad\left(\mathrm{k}_{\mathrm{r}}>5\right)
$$

Generally if we let $A(s, s+2)$ denote the set of positive integers with canonical representation

$$
\mathrm{F}_{\mathrm{k}_{1}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{\mathrm{s}+2}+\mathrm{F}_{\mathrm{s}} \quad\left(\mathrm{k}_{\mathrm{r}}>\mathrm{s}+3\right)
$$

and $\mathrm{A}(\mathrm{s}, \overline{\mathrm{s}+2})$ the set with canonical representation

$$
\mathrm{F}_{\mathrm{k}_{1}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{\mathrm{s}} \quad\left(\mathrm{k}_{\mathrm{r}}>\mathrm{s}+2\right)
$$

then we may state
Theorem 8. For $t \geq 1$ we have

$$
\begin{equation*}
a b^{t-1} a^{2}(\mathbb{N})=A(2 t, 2 t+2) \tag{5.8}
\end{equation*}
$$

$$
\begin{equation*}
a b^{t-1} a b(2)=A(2 t, 2 t+2) \tag{5.9}
\end{equation*}
$$

$$
\begin{align*}
& b^{t} a^{2}(\mathbb{N})=A(2 t+1, \overline{2 t+3})  \tag{5.10}\\
& b^{t} a b(\mathbf{N})=A(2 t+1,2 t+3) \tag{5.11}
\end{align*}
$$

The proof is by induction on $t$. For $t=1$, Eqs. (5.8) and (5.9) reduce to (5.6) and (5.7), respectively. Next by (5.5)

$$
\begin{equation*}
\mathrm{A}_{3}=\mathrm{ba}^{2}(\mathbb{N}) \cup \mathrm{bab}(\mathbb{N}) \tag{5.12}
\end{equation*}
$$

Let $n \in \mathrm{ba}^{2}(\mathrm{~N})$; then

$$
\mathrm{e}(\mathrm{n}) \in \mathrm{a}^{3}(\mathbb{N})=\mathrm{A}(2, \overline{4})
$$

that is,

$$
\mathrm{e}(\mathrm{n})=\mathrm{F}_{2}+\epsilon \mathrm{F}_{5}+\cdots
$$

where $\epsilon=0$ or 1 . This implies either

$$
\mathrm{n}=\mathrm{F}_{2}+\epsilon \mathrm{F}_{6}+\cdots \quad \text { or } \quad \mathrm{F}_{3}+\epsilon \mathrm{F}_{6}+\cdots
$$

The first possibility contradicts (5.3), so that

$$
\mathrm{ba}^{2}(\mathbb{N}) \subset \mathrm{A}(\mathrm{a}, \overline{5})
$$

Now take $\mathrm{n} \quad \mathrm{bab}(\mathbb{N})$, so that

$$
\begin{gathered}
\mathrm{e}(\mathrm{n}) \in \mathrm{a}^{2} \mathrm{~b}(\mathbb{N})=\mathrm{A}(2,4) \\
\mathrm{e}(\mathrm{n})=\mathrm{F}_{2}+\mathrm{F}_{4}+\epsilon \mathrm{F}_{6}+\cdots
\end{gathered}
$$

This implies either

$$
\mathrm{n}=\mathrm{F}_{2}+\mathrm{F}_{5}+\epsilon \mathrm{F}_{7}+\cdots \quad \text { or } \quad \mathrm{F}_{3}+\mathrm{F}_{5}+\epsilon \mathrm{F}_{7}+\cdots
$$

The first possibility cannot occur, so that

$$
(5.14) \quad \operatorname{bab}(\mathbb{N}) \subset A(3,5)
$$

Clearly (5.13) and (5.14) prove (5.10) and (5.11) for $t=1$.
We now assume that $(5.8), \cdots,(5.11)$ hold up to and including the value $t-1$. Let $n \in a b^{t-1} a^{2}(\mathbb{N})$, so that

$$
\mathrm{e}(\mathrm{n}) \in \mathrm{b}^{\mathrm{t}-1} \mathrm{a}^{2}(\mathbb{N})
$$

By the inductive hypothesis this gives

$$
\mathrm{e}(\mathrm{n}) \in \mathrm{A}(2 \mathrm{t}-1, \overline{2 \mathrm{t}+1})
$$

that is,

$$
e(n)=F_{2 t-1}+\epsilon F_{2 t+2}+\cdots
$$

This implies

$$
\mathrm{n}=\mathrm{F}_{2 \mathrm{t}}+\epsilon \mathrm{F}_{2 \mathrm{t}+3}+\cdots
$$

so that

$$
a b^{t-1} a^{2}(\mathbb{N}) \subset A(2 t, \overline{2 t+2)}
$$

Now take $n \in a b^{t-1} a b(N)$, so that

$$
\mathrm{e}(\mathrm{n}) \in \mathrm{b}^{\mathrm{t}-1} \mathrm{ab}(\mathbb{N})
$$

Hence by the inductive hypothesis

$$
\mathrm{e}(\mathrm{n}) \in \mathrm{A}(2 \mathrm{t}-1,2 \mathrm{t}+1)
$$

that is,

$$
\mathrm{e}(\mathrm{n})=\mathrm{F}_{2 \mathrm{t}-1}+\mathrm{F}_{2 \mathrm{t}+1}+€ \mathrm{~F}_{2 \mathrm{t}+3}+\cdots
$$

This implies

$$
\mathrm{n}=\mathrm{F}_{2 \mathrm{t}}+\mathrm{F}_{2 \mathrm{t}+2}=\epsilon \mathrm{F}_{2 \mathrm{t}+4}+\ldots,
$$

so that

$$
\begin{equation*}
a b^{t-1} a b(\mathbb{N}) \subset A(2 t, 2 t+2) \tag{5.16}
\end{equation*}
$$

In the next place, take $n \in b^{t} a^{2}(\mathbb{N})$, so that

$$
e(n) \in a b^{t-1} a^{2}(\mathbb{N})
$$

By (5.15) this gives

$$
\mathrm{e}(\mathrm{n}) \in \mathrm{A}(2 \mathrm{t}, \overline{2 \mathrm{t}+2})
$$

that is,

$$
e(n)=F_{2 t}+\epsilon F_{2 t+3}+\cdots
$$

Then either

$$
\mathrm{n}=\mathrm{F}_{2 \mathrm{t}+1}+\epsilon \mathrm{F}_{2 \mathrm{t}+4}+\cdots
$$

or

$$
\mathrm{n}=\mathrm{F}_{2}+\mathrm{F}_{4}+\cdots+\mathrm{F}_{2 \mathrm{t}}+\epsilon \mathrm{F}_{2 t+4}+\cdots
$$

The second possibility is ruled out, so that

$$
\begin{equation*}
a b^{t-1} a^{2}(\mathbb{N}) \subset A(2 t+1, \overline{2 t+3}) \tag{5.17}
\end{equation*}
$$

Finally take $n \in b^{t} a b(\mathbb{N})$, so that

$$
e(n) \in a b^{t-1} a b(\mathbb{N})
$$

Then by (5.16),

$$
e(n) \in A(2 t, 2 t+2)
$$

that is,

$$
\mathrm{e}(\mathrm{n})=\mathrm{F}_{2 \mathrm{t}}+\mathrm{F}_{2 \mathrm{t}+2}+\epsilon \mathrm{F}_{2 \mathrm{t}+4}+\cdots
$$

Then either

$$
n=F_{2 t+1}+F_{2 t+3}+\epsilon F_{2 t+5}+\cdots
$$

or

$$
\mathrm{n}=\mathrm{F}_{2}+\mathrm{F}_{4}+\cdots+\mathrm{F}_{2 \mathrm{t}}+\mathrm{F}_{2 \mathrm{t}+3}+\epsilon \mathrm{F}_{2 \mathrm{t}+5}+\cdots
$$

Again the second possibility is ruled out, so that

$$
\begin{equation*}
b^{t} a b(\mathbb{N}) \in A(2 t+1,2 t+3) \tag{5.18}
\end{equation*}
$$

Combining (5.15), (5.16), (5.17), (5.18), it is clear that we have completed the induction.

We define a function $\lambda(N)$ by means of $\lambda(1)=0$ and $\lambda(N)=t$, where $\mathrm{N}>1$ and t is the smallest integer such that

$$
\begin{equation*}
\mathrm{e}^{\mathrm{t}}(\mathrm{~N})=1 \tag{5.19}
\end{equation*}
$$

Theorem 9. Let

$$
\begin{equation*}
\mathrm{N}=\mathrm{F}_{\mathrm{k}_{1}}+\mathrm{F}_{\mathrm{k}_{2}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}} \tag{5.20}
\end{equation*}
$$

where

$$
k_{j}-k_{j+1} \geq 2 \quad(j=1, \cdots, r-1) ; \quad k_{r} \geq 2
$$

be the canonical representation of N. Then

$$
\lambda(N)= \begin{cases}k_{r}-2 & (r=1)  \tag{5.21}\\ k_{r}-1 & (r \geq 1)\end{cases}
$$

Proof.

1. $r=1$. Clear.
2. $\mathrm{r}=2, \mathrm{~N}=\mathrm{F}_{\mathrm{k}_{1}}+\mathrm{F}_{\mathrm{k}_{2}}$.

$$
\begin{gathered}
e^{k_{2}-2}(N)=F_{k_{1}-k_{2}+2}+F_{2} \\
e^{k_{r} k_{2}-2 k_{2}^{-2}} e^{(N)}=F_{4}+F_{2} \\
e^{k_{1}-3}(N)=F_{3}+F_{2}=F_{4} \\
e^{k_{1}-2}(N)=F_{3} \\
e^{k_{1}-1}(N)=F_{2}=1
\end{gathered}
$$

3. $r>2$. By induction.

Let $\Lambda_{t}$ denote the set of positive integers $N$ such that

$$
\begin{equation*}
\lambda(N)=t . \tag{5.22}
\end{equation*}
$$

Theorem 10. $\Lambda_{t}$ consists of the integers $N$ such that

$$
\begin{equation*}
F_{t+1}<N \leq F_{t+2} \tag{5.23}
\end{equation*}
$$

Thus

$$
\begin{equation*}
\left|\Lambda_{t}\right|=F_{t} \tag{5.24}
\end{equation*}
$$

Proof. Let N satisfy (4.22) and assume that N has the canonical representation (5.20). By (5.21) the value $N=F_{t+2}$ satisfies (5.22). For all other values of $N$, it is clear that $r>1$. Moreover since

$$
\begin{aligned}
& \mathrm{F}_{2}+\mathrm{F}_{4}+\cdots+\mathrm{F}_{2 \mathrm{~s}}=\mathrm{F}_{2 \mathrm{~s}+1}-1 \\
& \mathrm{~F}_{3}+\mathrm{F}_{4}+\cdots+\mathrm{F}_{2 \mathrm{~s}-1}=\mathrm{F}_{2 \mathrm{~s}}-1
\end{aligned}
$$

it is clear that N must satisfy

$$
\begin{equation*}
\mathrm{F}_{\mathrm{t}+1}<\mathrm{N}<\mathrm{F}_{\mathrm{t}+2} \tag{5.25}
\end{equation*}
$$

Conversely all N that satisfy (5.25) are of the form (5.20) with $\mathrm{r}>1$. This evidently completes the proof.

Finally we state
Theorem 11. Let $\{x\}=x-[x]$ denote the fractional part of the real number x . Then

$$
\begin{align*}
& \mathrm{N} \in \mathrm{a}(\mathbb{N}) \nLeftarrow 0<\left\{\frac{\mathrm{N}}{\alpha^{2}}\right\}<\frac{1}{\alpha}  \tag{5.26}\\
& \mathrm{~N} \in \mathrm{~b}(\mathbb{N}) \nLeftarrow \frac{1}{\alpha}<\left\{\frac{\mathrm{N}}{\alpha^{2}}\right\}<1 . \tag{5.27}
\end{align*}
$$

Proof. We recall that

$$
\mathrm{a}(\mathrm{n})=[\alpha \mathrm{n}], \quad \mathrm{b}(\mathrm{n})=\left[\alpha^{2} \mathrm{n}\right]
$$

Thus $N=b(n)$ is equivalent to

$$
\alpha^{2} \mathrm{n}=\mathrm{N}+\epsilon \quad(0<\epsilon<1)
$$

so that

$$
\frac{\mathrm{N}}{\alpha^{2}}=\mathrm{n}-\frac{\epsilon}{\alpha^{2}}
$$

Thus

$$
1 \geq\left\{\frac{N}{\alpha^{2}}\right\}=1-\frac{\epsilon}{\alpha^{2}}>1-\frac{1}{\alpha^{2}}=\frac{1}{\alpha}
$$

Conversely if

$$
\frac{1}{\alpha}<\left\{\frac{\mathrm{N}}{\alpha^{2}}\right\}
$$

then

$$
\frac{\mathrm{N}}{\alpha^{2}}=m+\epsilon, \quad \frac{1}{\alpha}<\epsilon<1 .
$$

Thus

$$
\mathrm{N}=\alpha^{2} \mathrm{~m}+\alpha^{2} \epsilon
$$

so that

$$
\alpha^{2}(\mathrm{~m}+1)=\mathrm{N}+\alpha^{2}(1-\epsilon)
$$

Since

$$
\alpha^{2}(1-\epsilon)<\alpha^{2}\left(1-\frac{1}{\alpha}\right)=\alpha-1<1
$$

it follows that $b(m+1)=N$.
This proves (5.27). The equivalence (5.26) follows from (5.27) since

$$
a(\mathbb{N}) \cup b(\mathbb{N})=\mathbb{N}
$$

## 6. WORD FUNCTIONS

By a word function (or briefly a word) is meant any monomial in the a's and b's. It is convenient to include 1 as a word. Clearly if $u, v$ are any words, then $a u \neq b v$. Also if $a u=a v$ or $b u=b v$ then $u=v$. It follows readily that any word is uniquely represented as a product of "primes" a, b.

We define the weight of a word by means of

$$
\begin{equation*}
p(1)=0, \quad p(a)=1, \quad p(b)=2 \tag{6.1}
\end{equation*}
$$

together with

$$
\begin{equation*}
p(u v)=p(u)+p(v) \tag{6.2}
\end{equation*}
$$

where $u, v$ are arbitrary words. Thus there is exactly one word of weight 1 , two of weight 2 , and three of weight 3 . Let $N_{p}$ denote the number of words of weight $p$. If $w$ is any word of weight $p$, then, for $p>2, w=$ au or bv, where $u$ is of weight $p-1, v$ of weight $p-2$. Hence

$$
N_{p}=N_{p-1}+N_{p-2} \quad(p \geq 2)
$$

It follows that

$$
\begin{equation*}
N_{p}=F_{p+1} \quad(p \geq 0) \tag{6.3}
\end{equation*}
$$

the number of words of weight $p$ is equal to the Fibonacci number $F_{p+1}$. Consider the equation

$$
\begin{equation*}
u v=v u . \tag{6.4}
\end{equation*}
$$

We may assume without loss of generality that $p(u) \geq p(v)$. It then follows from the unique factorization property that $u=v z$, where $z$ is some word. Thus $\mathrm{vzv}=\mathrm{v}^{2} \mathrm{z}$, so that $\mathrm{zv}=\mathrm{vz}$. Thus by an easy induction on the total weight of uv we get the following theorem.

Theorem 12. The words $u, v$ satisfy (6.4) if and only if there is a word $w$ such that $u=w^{r}, v=w^{s}$, where $r, s$ are nonnegative integers. We show next that any word is "almost" linear. More precisely we prove

Theorem 13. Any word $w$ of weight $p$ is uniquely representable in the form

$$
\begin{equation*}
\mathrm{u}(\mathrm{n})=\mathrm{F}_{\mathrm{p}} \mathrm{a}(\mathrm{n})+\mathrm{F}_{\mathrm{p}-1} \mathrm{n}-\lambda_{\mathrm{u}}, \tag{6.5}
\end{equation*}
$$

where $\lambda_{u}$ is independent of $n$.
Proof. We have

$$
\begin{gathered}
b(n)=a(n)+n \\
a^{2}(n)=a(n)+n-1, \\
a b(n)=2 a(n)+n \\
b a(n)=2 a(n)+n-1 .
\end{gathered}
$$

We accordingly assume the truth of (6.5) for words $u$ of weight $<p$. There are two cases to consider. (i) if $u=v a$, then $v$ is of weight $p-1$, so that (6.5) gives

$$
\mathrm{v}(\mathrm{n})=\mathrm{F}_{\mathrm{p}-1} \mathrm{a}(\mathrm{n})+\mathrm{F}_{\mathrm{p}-2} \mathrm{n}-\lambda_{\mathrm{v}} .
$$

$$
\begin{aligned}
u(n)=v a(n) & =F_{p-1} a^{2}(n)+F_{p-2} a(n)-\lambda_{v} \\
& =F_{p} a(n)+F_{p-1} n-\lambda_{v}-F_{p-1}
\end{aligned}
$$

(ii) if $\mathrm{u}=\mathrm{vb}, \mathrm{v}$ is of weight $\mathrm{p}-2$, so that

$$
\mathrm{v}(\mathrm{n})=\mathrm{F}_{\mathrm{p}-2} \mathrm{a}(\mathrm{n})+\mathrm{F}_{\mathrm{p}-3} \mathrm{n}-\lambda_{\mathrm{v}} .
$$

Then

$$
\begin{aligned}
u(n)=v b(n) & =F_{p-2} a b(n)+F_{p-3} b(n)=\lambda_{v} \\
& =F_{p-2}(2 a(n)+n)+F_{p-3}(a(n)+n)-\lambda_{v} \\
& =\left(2 F_{p-2}+F_{p-3}\right) a(n)+\left(F_{p-2}+F_{p-3}\right) n-\lambda_{v} \\
& =F_{p} a(n)+F_{p-1} n-\lambda_{v} .
\end{aligned}
$$

This completes the induction.
We now show that the representation (6.5) is unique. Otherwise there exist numbers $r, s, t$ such that

$$
\mathrm{ra}(\mathrm{n})+\mathrm{sn}=\mathrm{t} .
$$

Taking $\mathrm{n}=1,2,3$ we get

$$
\left\{\begin{array}{c}
\mathrm{r}+\mathrm{s}=\mathrm{t} \\
3 \mathrm{r}+2 \mathrm{~s}=\mathrm{t} \\
4 \mathrm{r}+3 \mathrm{~s}=\mathrm{t}
\end{array}\right.
$$

and therefore $r=s=t=0$.
Incidentally, we have proved that $\lambda_{\mathrm{u}}$ satisfies

$$
\begin{equation*}
\lambda_{\mathrm{va}}=\lambda_{\mathrm{v}}+\mathrm{F}_{\mathrm{p}}, \quad \lambda_{\mathrm{vb}}=\lambda_{\mathrm{v}} \tag{6.6}
\end{equation*}
$$

where $v$ is of weight p. Note that

$$
\lambda_{v a b}=\lambda_{v a}=\lambda_{v}+F_{p}, \quad \lambda_{v b a}=\lambda_{v b}+F_{p+1}=\lambda_{v}+F_{p+1}
$$

Note also that (6.5) implies

$$
\begin{equation*}
\lambda_{u}=F_{p+1}-u(1) \tag{6.7}
\end{equation*}
$$

As an immediate corollary of Theorem 13 we have Theorem 14. For arbitrary words, $u, v$, we have

$$
\begin{equation*}
u v-v u=C \tag{6.8}
\end{equation*}
$$

where $C$ is independent of $n$.
It may be of interest to mention a few special cases of (6.5):

$$
\begin{align*}
& \mathrm{a}^{\mathrm{k}}(\mathrm{n})=\mathrm{F}_{\mathrm{k}} \mathrm{a}(\mathrm{n})+\mathrm{F}_{\mathrm{k}-1} \mathrm{n}-\mathrm{F}_{\mathrm{k}+1}+1,  \tag{6.9}\\
& \mathrm{~b}^{\mathrm{k}}(\mathrm{n})=\mathrm{F}_{2 \mathrm{k}} \mathrm{a}(\mathrm{n})+\mathrm{F}_{2 \mathrm{k}-1} \mathrm{n},  \tag{6.10}\\
& b^{k}(n)=a^{2 k}(n)+F_{2 k+1}-1,  \tag{6.11}\\
& (\mathrm{ab})^{\mathrm{k}}(\mathrm{n})=\mathrm{F}_{3 \mathrm{k}} \mathrm{a}(\mathrm{n})+\mathrm{F}_{3 \mathrm{k}-1} \mathrm{n}-\frac{1}{2}\left(\mathrm{~F}_{3 \mathrm{k}-1}-1\right),  \tag{6.12}\\
& (b a)^{k}(\mathrm{n})=\mathrm{F}_{3 \mathrm{k}} \mathrm{a}(\mathrm{n})+\mathrm{F}_{3 \mathrm{k}-1} \mathrm{n}-\mathrm{F}_{3 \mathrm{k}-1} \text {, }  \tag{6.13}\\
& (a b)^{k}(n)-(b a)^{k}(n)=\frac{1}{2}\left(F_{3 k-1}+1\right),  \tag{6.14}\\
& a^{k} b^{j}(n)=F_{2 j+k^{a}}{ }^{(n)}+F_{2 j+k-1} n-F_{k+1}+1,  \tag{6.15}\\
& b^{j}{ }_{\mathrm{a}}{ }^{\mathrm{k}}(\mathrm{n})=\mathrm{F}_{2 \mathrm{j}+\mathrm{k}} \mathrm{a}(\mathrm{n})+\mathrm{F}_{2 j+\mathrm{k}-1} \mathrm{n}^{\mathrm{n}}-\mathrm{F}_{2 \mathrm{j}+\mathrm{k}+1}+\mathrm{F}_{2 \mathrm{j}+1} \text {, }  \tag{6.16}\\
& a^{k} b^{j}(n)-b^{j}{ }^{j}{ }^{k}(n)=F_{2 j+k+1}-F_{2 j+1}-F_{k+1}+1 . \tag{6.17}
\end{align*}
$$

## 7. GENERATING FUNCTIONS

Put
(7.1) $\quad \phi_{j}(x)=\sum_{n \in A_{j}} x^{n}$

$$
(\mathrm{j}=2,3,4, \cdots)
$$

In view of (4.5) and (4.6), Eq. (5.1) is equivalent to

$$
\begin{equation*}
\phi_{2 r}(x)=\sum_{n=1}^{\infty} x^{a b^{r-1} a(n)} \tag{7.2}
\end{equation*}
$$

and

$$
\begin{equation*}
\phi_{2 r+1}(x)=\sum_{n=1}^{\infty} x^{b^{r} a(n)} \tag{7.3}
\end{equation*}
$$

Also it is clear that

$$
\begin{equation*}
\frac{\mathrm{x}}{1-\mathrm{x}}=\sum_{\mathrm{j}=0}^{\infty} \phi_{\mathrm{j}}(\mathrm{x}) \tag{7.4}
\end{equation*}
$$

It follows from the definition of $A_{r}$ that
(7.5) $\quad \phi_{r}(x)=\mathrm{x}^{\mathrm{F}_{\mathrm{r}}}\left\{1+\sum_{\mathrm{j}=\mathrm{r}+2}^{\infty} \phi_{\mathrm{j}}(\mathrm{x})\right\} \quad(\mathrm{r}=2,3,4, \cdots)$.

This evidently implies

In particular, by (7.5),

$$
\phi_{2}(x)=x\left\{1+\sum_{j=4}^{\infty} \phi_{j}(x)\right\}
$$

Combining this with (5.4), we get

$$
\begin{equation*}
(1+\mathrm{x}) \phi_{2}(\mathrm{x})+\mathrm{x} \phi_{3}(\mathrm{x})=\frac{\mathrm{x}}{1-\mathrm{x}} \tag{7.7}
\end{equation*}
$$

It is convenient to define

$$
\begin{equation*}
\phi(\mathrm{x})=\sum_{\mathrm{n}=1}^{\infty} \mathrm{x}^{\mathrm{a}(\mathrm{n})} \tag{7.8}
\end{equation*}
$$

Since the set $a(\mathbb{N})$ is the union of the sets $a^{2}(\mathbb{N})$ and $a b(\mathbb{N})$, it follows from (3.4) that

$$
\begin{equation*}
\phi(\mathrm{x})=\phi_{2}(\mathrm{x})+\mathrm{x} \phi_{3}(\mathrm{x}) . \tag{7.9}
\end{equation*}
$$

Therefore by (7.7), we have

$$
\begin{equation*}
\mathrm{x} \phi_{2}(\mathrm{x})=\frac{\mathrm{x}}{1-\mathrm{x}}-\phi(\mathrm{x}) \tag{7.10}
\end{equation*}
$$

and

$$
\begin{equation*}
\mathrm{x}^{2} \phi_{3}(\mathrm{x})=\frac{\mathrm{x}}{1-\mathrm{x}}+(1+\mathrm{x}) \phi(\mathrm{x}) \tag{7.11}
\end{equation*}
$$

Making use of (7.5), (7.10) and (7.11) we can express all $\phi_{j}(x)$ in terms of $\phi(x)$. For example, since

$$
x^{-1} \phi_{2}(x)-x^{-2} \phi_{3}(x)=\phi_{4}(x)
$$

we get

$$
\begin{equation*}
\mathrm{x}^{4} \phi_{4}(\mathrm{x})=\frac{\mathrm{x}+\mathrm{x}^{3}}{1-\mathrm{x}}-\left(1+\mathrm{x}+\mathrm{x}^{2}\right) \phi(\mathrm{x}) \tag{7.12}
\end{equation*}
$$

Generally we have
(7.13)

$$
\mathrm{x}^{\mathrm{F}_{\mathrm{r}+1^{-1}} \phi_{\mathrm{r}}(\mathrm{x})=(-1)^{\mathrm{r}}\left\{\frac{\mathrm{xA} \mathrm{r}_{\mathrm{r}}(\mathrm{x})}{1-\mathrm{x}}-\mathrm{B}_{\mathrm{r}}(\mathrm{x}) \phi(\mathrm{x})\right\}, ~, ~}
$$

where $A_{r}(x), B_{r}(x)$ are polynomials that satisfy

$$
\left\{\begin{array}{l}
A_{r+2}(x)=A_{r+1}(x)+x^{F_{r+1}} A_{r}(x)  \tag{7.14}\\
\mathbb{B}_{r+2}(x)=B_{r+1}(x)+x^{r+1} B_{r}(x)
\end{array}\right.
$$

together with the initial conditions

$$
\begin{cases}\mathrm{A}_{2}(\mathrm{x})=1, & \mathrm{~A}_{3}(\mathrm{x})=1, \\ \mathrm{~B}_{2}(\mathrm{x})=1, & \mathrm{~B}_{3}(\mathrm{x})=1+\mathrm{x} .\end{cases}
$$

It follows readily that

$$
\begin{equation*}
\mathrm{B}_{\mathrm{r}}(\mathrm{x})=\frac{1-\mathrm{x}^{\mathrm{F}} \mathrm{r}}{1-\mathrm{x}} \tag{7.15}
\end{equation*}
$$

while

$$
\begin{equation*}
x A_{r}(x)=\sum_{j=1}^{F_{r-1}} x^{a(j)} \tag{7.16}
\end{equation*}
$$

In conclusion we shall show that the function $\phi(x)$ cannot be continued across the unit circle. Indeed by a known theorem [1, p. 315], either $\phi(x)$ is rational or it has the unit circle for a natural boundary. Moreover, it is rational if and only if, for some positive integer m ,

$$
\left(1-x^{\mathrm{m}}\right) \phi(\mathrm{x})=\mathrm{P}(\mathrm{x})
$$

where $P(x)$ is a polynomial. Clearly the coefficients of $P(x)$ are rational integers. It follows that

$$
\begin{equation*}
\lim _{x}(1-x) \phi(x)=C, \tag{7.18}
\end{equation*}
$$

where $C$ is rational. On the other hand, if we put

$$
\phi(x)=\sum_{k=1}^{\infty} c_{k} x^{k}
$$

so that $c_{k}=0$ or 1 , it is evident from (7.8) that

$$
\sum_{k=1}^{n} c_{k} \sim \frac{n}{\alpha}
$$

Since this implies

$$
\lim _{x}(1-x) \phi(x)=\frac{1}{\alpha}
$$

we have a contradiction with (7.18).

## 8. APPENDIX

In addition to the canonical representation (1.1) we have another representation described in the following

Theorem 15. Every integer N is uniquely represented in the form

$$
\begin{equation*}
\mathrm{N}=\mathrm{F}_{\mathrm{k}_{1}}+\cdots+\mathrm{F}_{\mathrm{k}_{\mathrm{r}}}+\mathrm{F}_{2 \mathrm{k}+1} \quad(\mathrm{k} \geq 0) \tag{8.1}
\end{equation*}
$$

where

$$
k_{j}-k_{j+1} \geq 2 \quad(j=1, \cdots, r-1), \quad k_{r}-(2 k+1) \geq 2
$$

Proof. By (5.2),
(8.2)

$$
a(\mathbb{N})=\bigcup_{t=1}^{\infty} A_{2 t}
$$

Hence, by the first proof of Theorem 6,

$$
\mathbb{N}=\bigcup_{t=1}^{\infty} A_{2 t-1} .
$$

This evidently proves the theorem.
We may refer to (8.1) as the second canonical representation of $N$.
In view of Theorem 15, we let $\overline{\mathrm{A}}_{2 \mathrm{k}+1}$ denote the set of positive integers $\{N\}$ of the form (8.1). Then the sets

$$
\overline{\mathrm{A}}_{2 \mathrm{k}+1} \quad(\mathrm{k}=0,1,2, \cdots)
$$

constitute a partition of the positive integers. Clearly
(8.3) $\quad \overline{\mathrm{A}}_{2 \mathrm{k}+1}=\mathrm{A}_{2 \mathrm{k}+1} \quad(\mathrm{k}=1,2,3, \cdots)$,
while

$$
\begin{equation*}
\bar{A}_{1}=\bigcup_{t=1}^{\infty} A_{2 t}=a(\mathbb{N}) \tag{8.4}
\end{equation*}
$$

For $N \in \bar{A}_{1}$, if
(8.5)

$$
\begin{gathered}
N=F_{k_{1}}+\cdots+F_{k_{r}}+F_{1} \\
k_{j}-k_{j+1} \geq 2 \quad(j=1, \cdots, r-1), \quad k_{r}>3
\end{gathered}
$$

then clearly we may replace $\mathrm{F}_{1}$ by $\mathrm{F}_{2}$ and $(8.5)$ reduces to the first canonical representation. In this case, then, $N \in A_{2}$. However, if $k_{r}=3$, the situation is less simple. For example

$$
8=F_{6}=F_{5}+F_{3}+F_{1}
$$

Generally, since

$$
\mathrm{F}_{1}+\mathrm{F}_{3}+\mathrm{F}_{5}+\cdots+\mathrm{F}_{2 \mathrm{~s}-1}=\mathrm{F}_{2 \mathrm{~s}}
$$

it follows that if the number N has the second canonical representation

$$
\mathrm{N}=\mathrm{F}_{1}+\mathrm{F}_{3}+\cdots+\mathrm{F}_{2 \mathrm{~s}-1}+\mathrm{F}_{\mathrm{k}_{1}}+\mathrm{F}_{\mathrm{k}_{2}}+\cdots,
$$

where

$$
k_{j+1}-k_{j} \geq 2 \quad(j \geq 1), \quad k_{1} \geq 2 s+2,
$$

then $N \in A_{2 s}$ and conversely.
