Let $S\left(X^{2}\right)_{q}$ symbolize the sum of the digits of $X^{2}$ on the base $q$. For example, $S\left(9^{2}\right)_{5}=S\left(14^{2}\right)_{5}=5$ since $9_{5}^{2}=311$.

The following is a method for finding $q$ such that $S\left(X^{2}\right)_{q}=X$ when $X$ is given. For example $\mathrm{S}\left(7^{2}\right)_{8}=7$ since $7_{8}^{2}=61$.

Step 1. List all the factors of X except X itself.
Step 2. List all the factors of $\mathrm{X}-1$.
Step 3. Multiply each factor of X by one of the factors of $\mathrm{X}-1$, discarding all products greater than $X-1$. The retained products are the ten's digits of the $X_{q}^{2}$ that we seek.

Step 4. The unit's digits can be obtained by simple subtraction of the quantities in three from X .

Step 5. q can now be computed by simple arithmetic.
Example. $S\left(21^{2}\right)_{q}=21$. Find all values of $q$.
Step I:
$\begin{array}{lll}1 & 3 & 7\end{array}$
$\begin{array}{lllllll}\text { Step II: } & 1 & 2 & 4 & 5 & 10 & 20\end{array}$
Step III: $\quad 1 \begin{array}{llllll} & 2 & 4 & 5 & 10 & 20\end{array}$
$\begin{array}{llll}3 & 6 & 12 & 15\end{array}$
$7 \quad 14$
Step IV: $\quad 1(20) \quad 2(19) \quad 4(17) \quad 5(16) \quad 10(11) \quad 20(1)$
$3(18) \quad 6(15) \quad 12(9) \quad 15(6) \quad 7(14) \quad 14(7)$
The quantities in parentheses are the unit's digits.
Step V: For example, for $5(16), 5 b+16=441$ in base ten so that $b=85$ expressed as a base ten number. The bases taken in order are

| 421 | 211 | 106 | 85 | 43 | 22 |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 141 | 71 | 36 | 29 | 61 | 31 |

The problem is: Why does this method work?
Harlan L. Umansky, Emerson High School, Union City, N. J. * *

If eleven alternate terms of any Fibonacci sequence are added and divided by $\mathrm{L}_{11}$ (199), the result is the middle term of the group of eleven terms added together.

Example. Using the series beginning 1, 4, $\cdots$,
$157+411+1076+2817+7375+19308+50549+132339+346468+907065+2374727=3942292$

Dividing by 199 gives 19308.
